## **Abstract**

Sama Field is one of the rare fields in the offshore Nile Delta which contain two types of hydrocarbons: gas and oil. Although Sama Field is covered by a state-of-the-art high density, long offset 3D dataset, the differentiation between several fluid types using the conventional stacked dataset is a big challenge. Although different fluids discrimination is difficult using post-stack seismic data, pre-stack seismic data can be the best tool of doing it. The reason can be attributed to the different amplitude change with offset behavior for each fluid type. The main aim is to find a way to map out the different reservoirs, in order to help in calculating the HIIP (Hydrocarbon Initial in Place) volumes and for optimizing the development plan. Rock physics modeling is needed to understand the AVO behaviors of oil and gas sands of the field. This understanding can be coupled with the pre-stack seismic data to produce AVO-classified seismic volumes. Hence, reservoirs of different fluid types can be identified and mapped across the study area. Rock physics modeling suggested that gas sand exhibits class 3 AVO response; however oil sand has a class 2 AVO behavior. Pre-stack seismic data needed some conditioning before the AVO classification. The conditioning workflow included: frequency filtering, time alignments, and amplitudes balancing. Finally AVO-classified seismic volumes have been produced, which enabled the lateral tracking of the different reservoir bodies away from the well. The integration of pre-stack seismic data and the understanding the AVO behavior of different fluids allows precise delineation for the different reservoirs. Which in turn promotes a better chance of success for further future development plan.

# Introduction

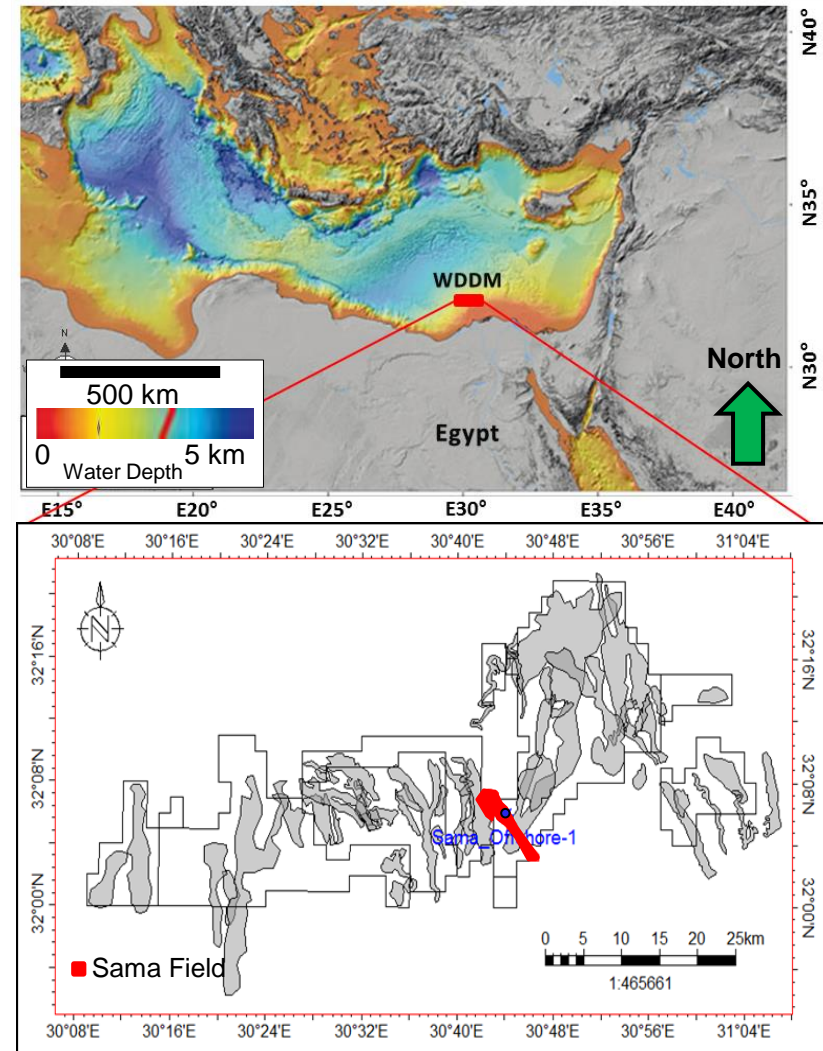

- Sama offshore field is located in WDDM, offshore Nile Delta and has been discovered by Sama Offshore-1 well.
- Structurally, it is a four-way dip closure, part of a rollover due to a drag on Rosetta fault.
- Stratigraphically, it is a Pliocene slope marine channel complex consisting of four seismically resolvable architectural elements.
- Pressure data suggests the presence of two fluid gradients in the hydrocarbon bearing reservoir interval.

# Area of Study

- Egypt
- Offshore Nile Delta
- West Delta Deep Marine (WDDM) leases covers 2212 km<sup>2</sup>
- The Sama offshore field is a Pliocene reservoir located 105 km off Alexandria under water depths around 450m.

(Modified from Mohamed et al., 2014)

# Outline

- Introduction
- Geological Setting
- Reservoir Characteristics
- AVO Modeling
- Conclusions

# Reservoir Characteristics

- Sama-Offshore is a complex submarine channel system draped over anticlinal form
- Sama-Offshore is 10 km long and up to 2.5 km wide at its widest point

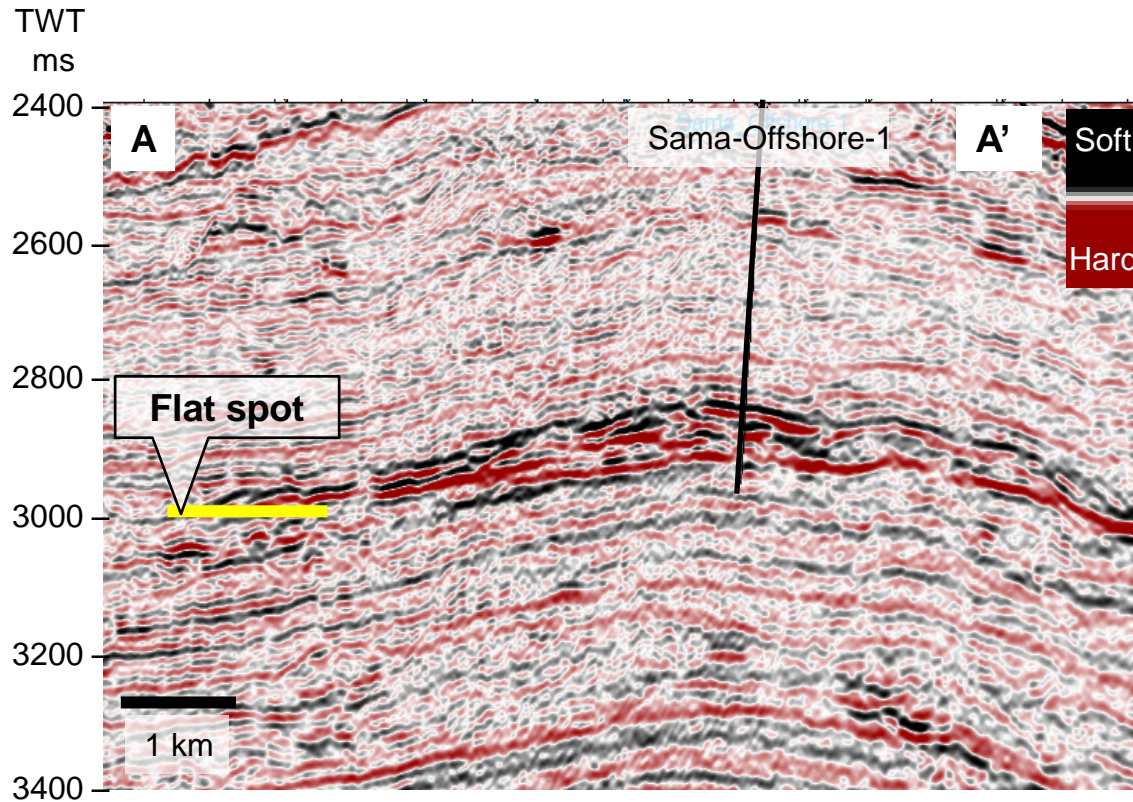

Seismic section followed by a sketch showing the multi channel phases

AAA attribute map from top to base reservoir showing the channel geometry

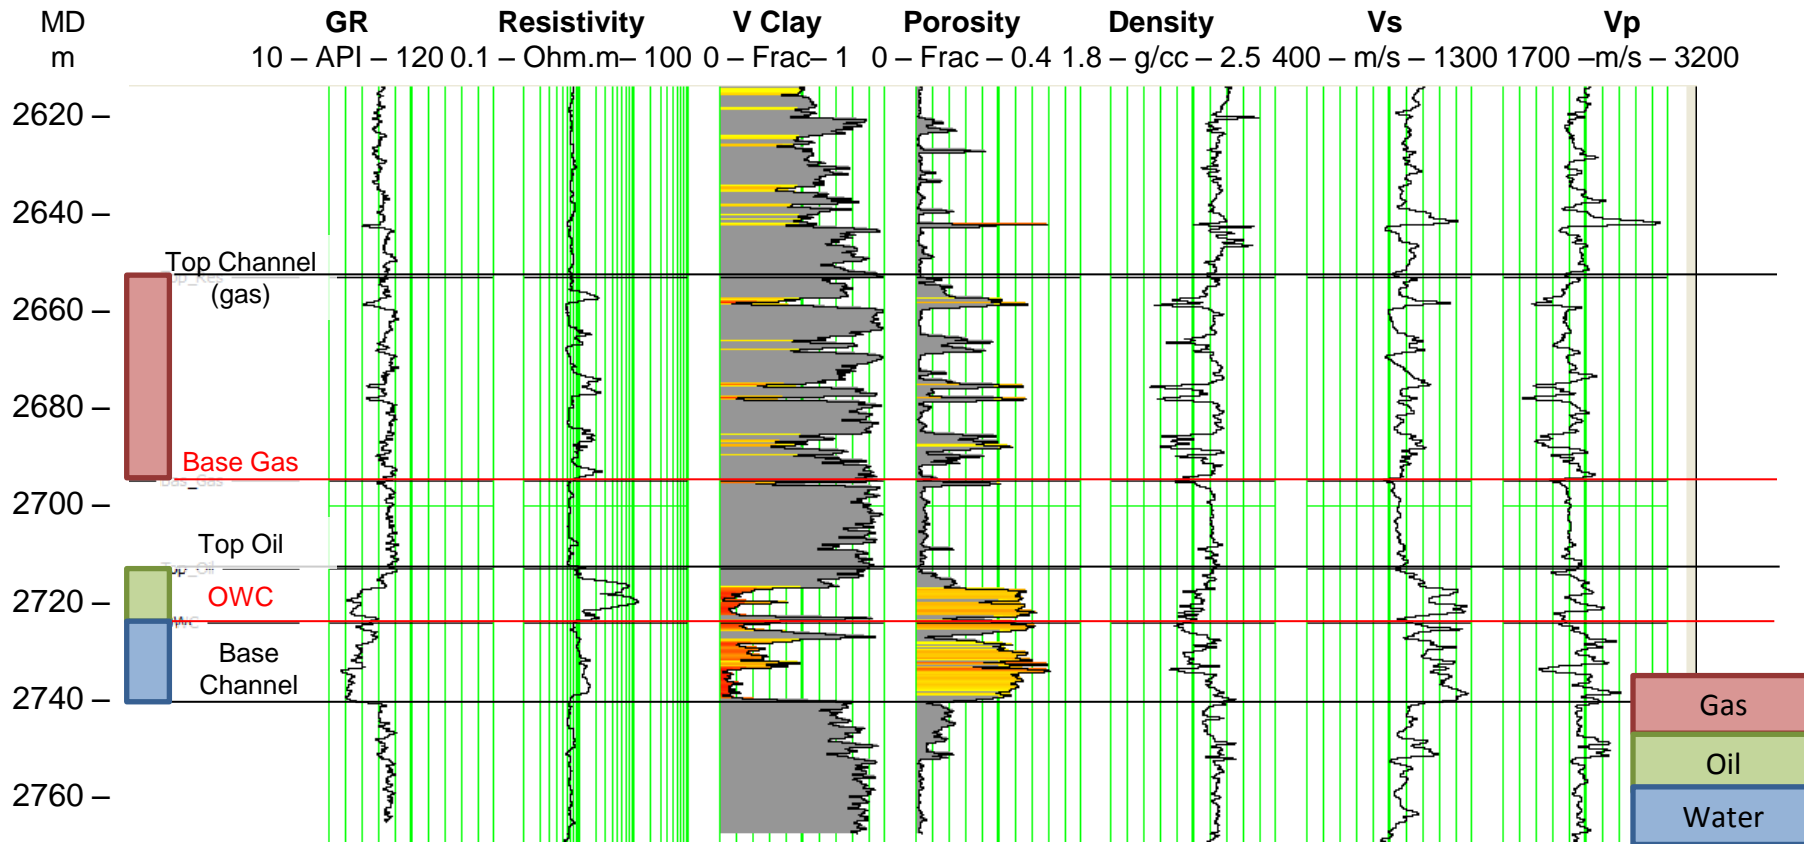

# Reservoir Characteristics

- Seismic section passing through Sama-Offshore field showing the 4-way dip closure

# Reservoir Characteristics

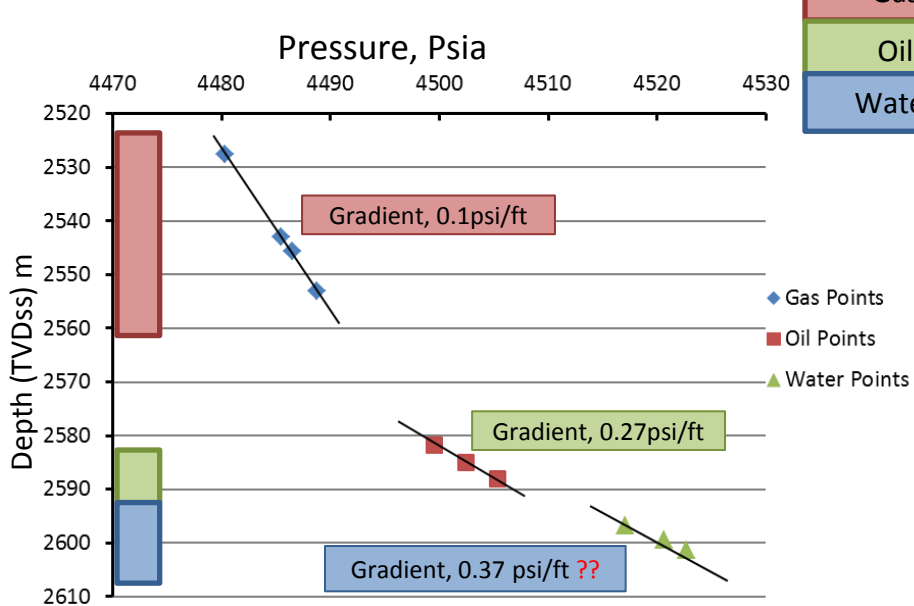

- Sama-Offshore is a channel that are up to 100m in gross thickness, 27m of pay
- An average reservoir porosity of 18%
- An average water saturation of 38%

# Reservoir Pressure Data

## Sama Offshore-1 Pressure Measurement

## Sama PVT analysis

Table 1  
Samples Listing and Validation

CHAMBER NUMBER	SEPARATOR PRESSURE (PSIG)	SEPARATOR TEMPERATURE (°F)	GAS OIL RATIO (SCF/STB)	Bo* (BBL/STB)	DENSITY AT 60 °F (GM/CC)	°API	GAS GRAVITY (AIR=1.000)
881015	0	60	763.8	1.2381	0.8330	38	0.653

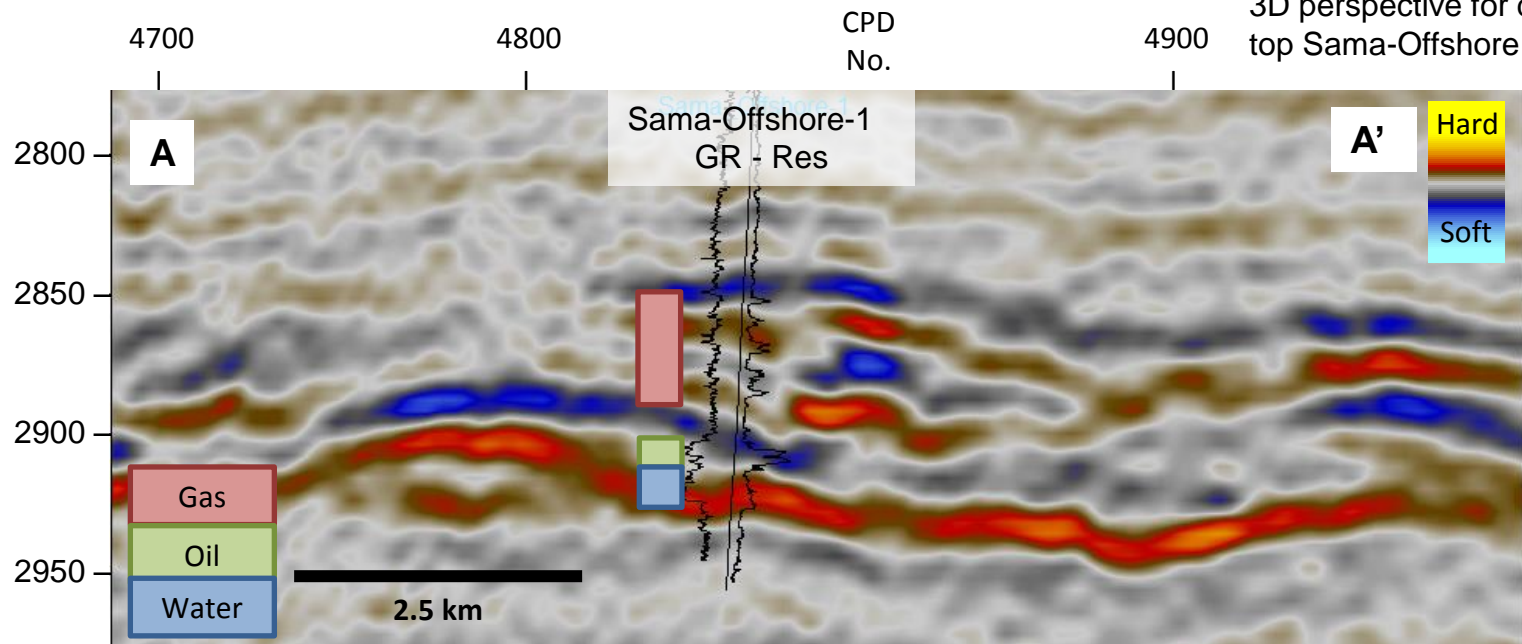

- MDT samples confirmed fluid types that were interpreted by test track gradients. MDT analysis confirmed the presence of gas gradient in the upper sand and oil gradient in the lower sand.
- From PVT analysis showed there is an oil zone with 38 API.

# Problem Statement

3D perspective for depth structure map of top Sama-Offshore with field polygon

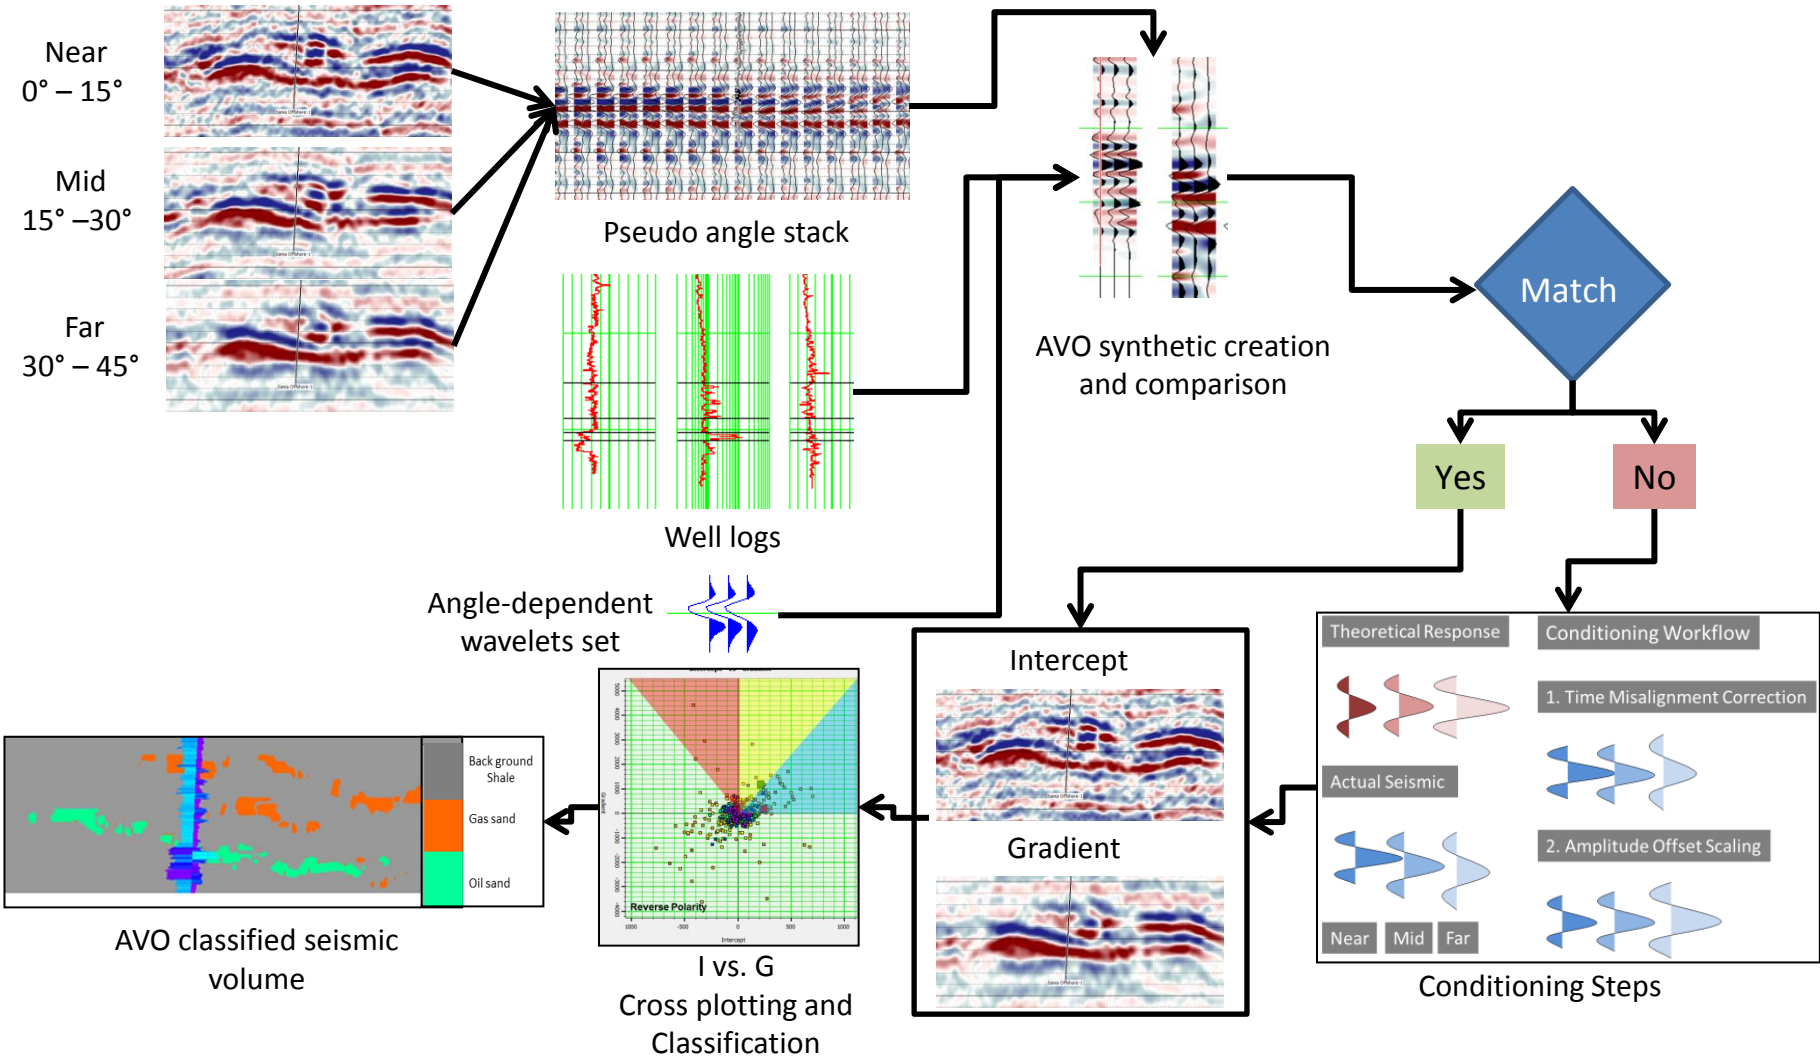

It is difficult to tell which is Oil and which is gas

# Outline

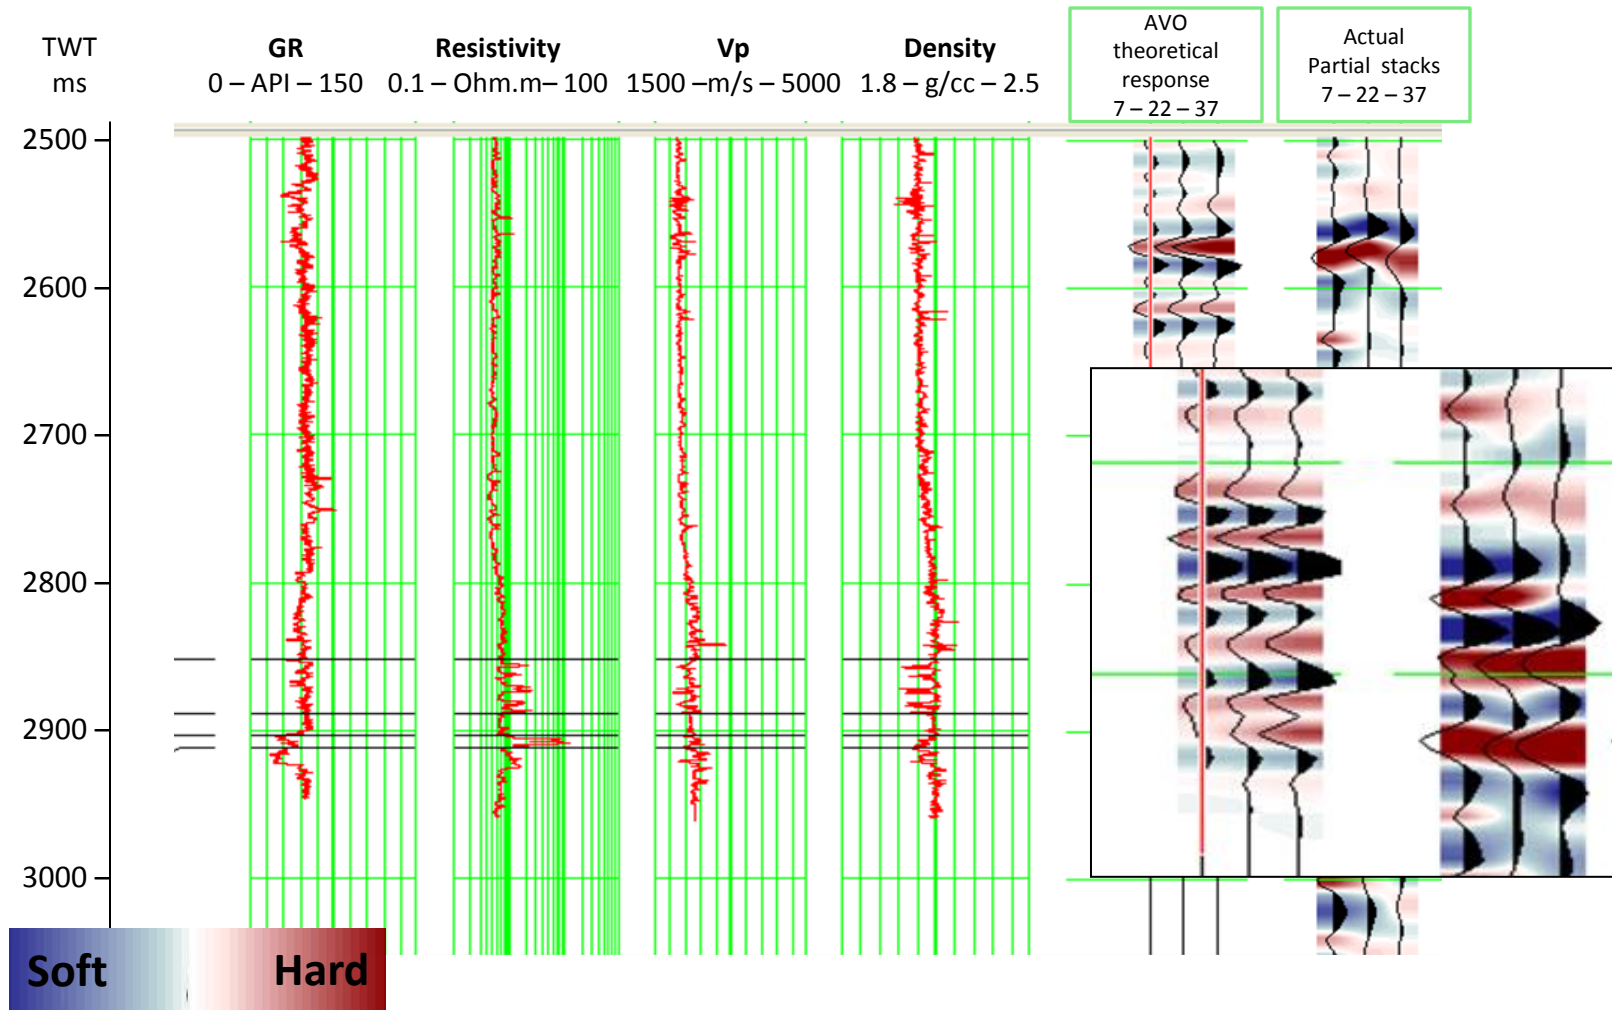

- Introduction
- Geological Setting
- Reservoir Characteristics
- AVO Modeling
- Conclusions

# Conclusions

- Sama-offshore well indicates that AVO signatures can be used as an integral part of seismic interpretation to predict hydrocarbon types.
- Sama- offshore well found that type 2 and 3 AVO behaviors are indicatives for the oil and gas response respectively.
- The proposed workflow is recommended to be applied in any similar geological setting.
- We can use AVO classified volume to predict the hydrocarbon geobodies which is important in volumetric calculation and in any further development wells.
