Abstract

Where is your next exploration or development idea coming from? Why not the next OCGS technical presentation? That is exactly where the technical methods were presented that took a tired, uneconomic prospect to a profitable venture.

An OCGS luncheon meeting unexpectedly unlocked a way to calculate the potential oil column of a low-perm Upper Pennsylvanian (Missourian) Lansing reservoir in the Oklahoma Panhandle of Hugoton Embayment, resulting in the patience to drill “one more well.” Ted Beaumont’s presentation in 2004 explained how capillary pressures and buoyancy pressure are related, and even measurable. This article shows the field development and the impact of the application on developing additional reserves.

From now on, I, John Brett, always try to take away some nugget from any presentation I attend; you should too. It might just pay dividends!

4. For a given drive mechanism

PORE THROAT PROFILES

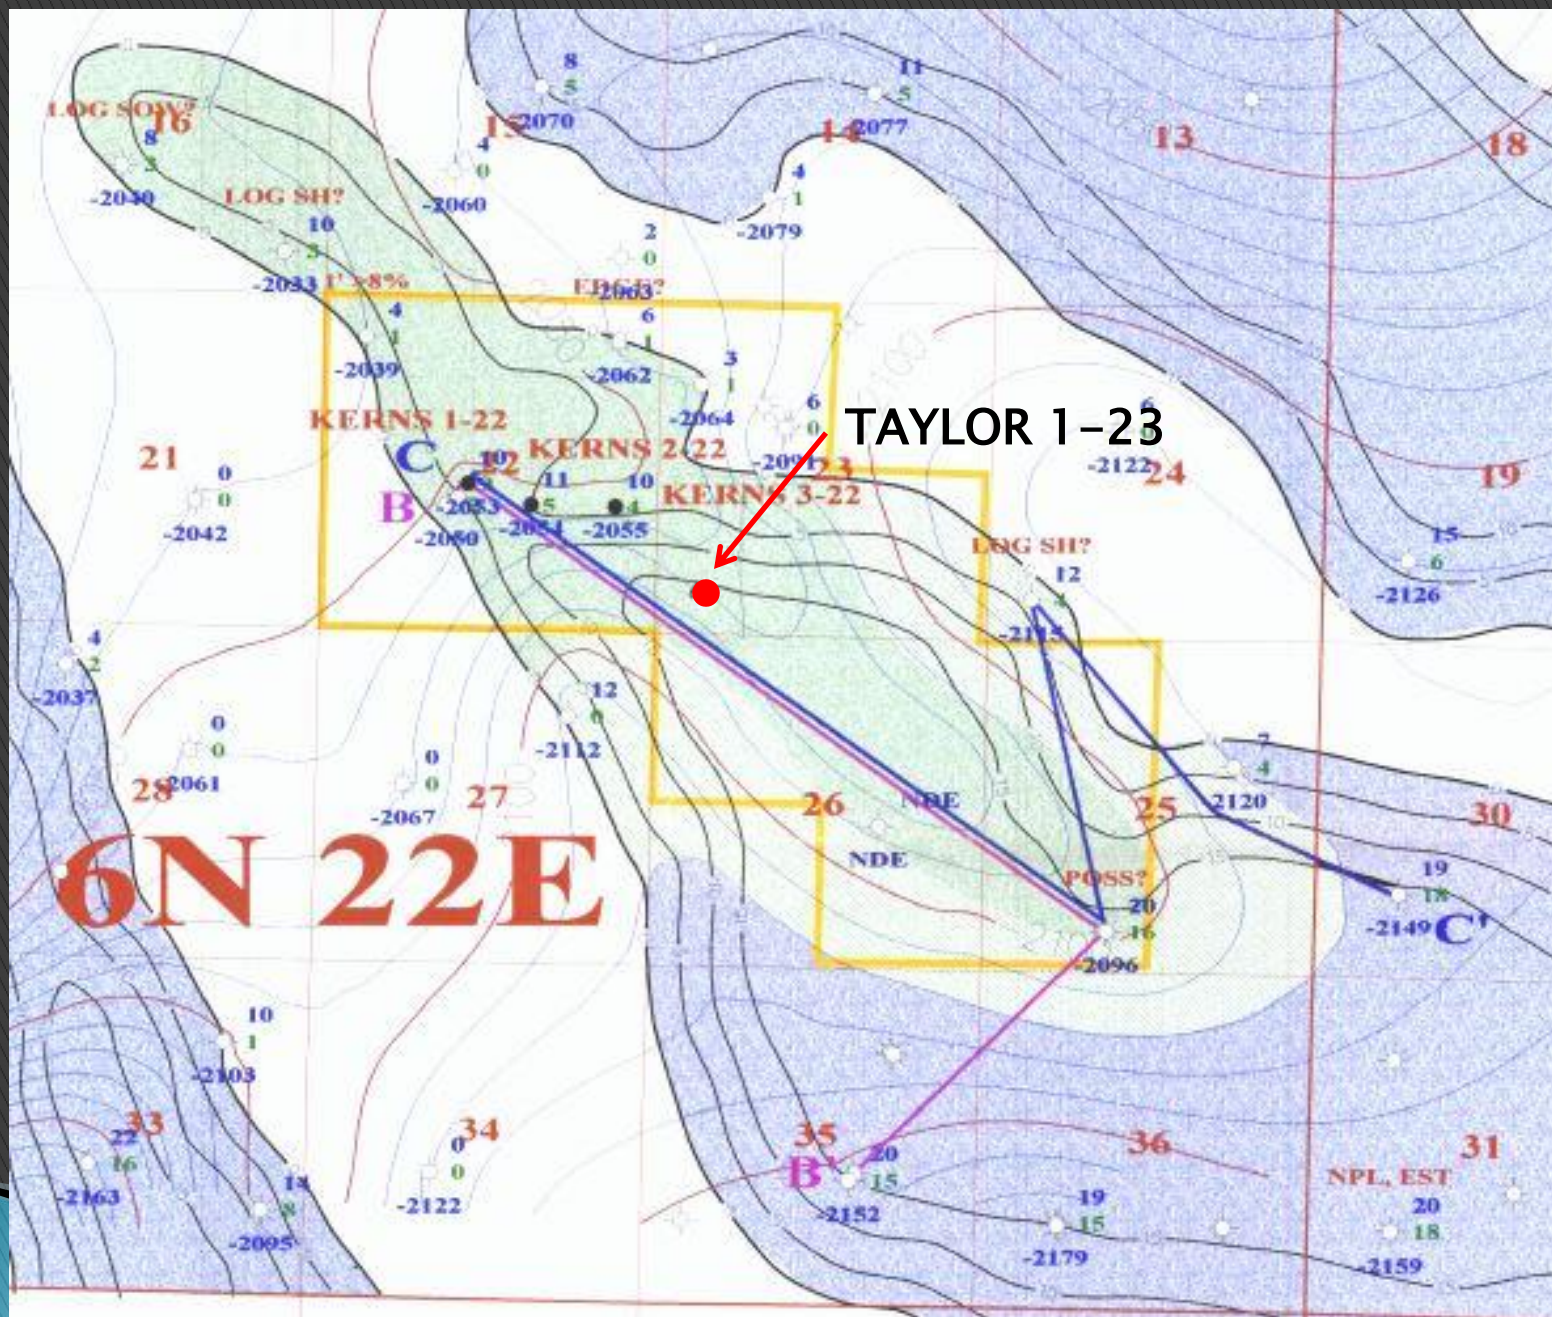

Calculating oil column height

What can we learn from this exercise?

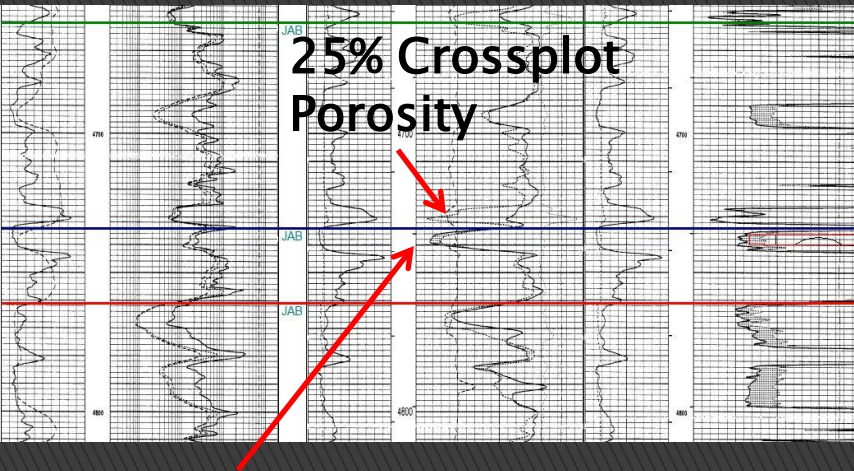

- ▶ Poorly connected Moldic porosity is suggesting a low permeability vs. porosity relationship.
- ▶ If the reservoir is homogeneous (which it is not), the oil height required to “squeeze” the oil into the low-perm rock would need to be 250' in height.
- ▶ The control suggests 250' oil column is impossible.
- ▶ There must be some better reservoir, with more connected pore throats, exerting the necessary buoyancy pressure.
- ▶ Yes– DRILL ONE MORE WELL!

Finally Economic!

Porosity vs Perm Plots are important

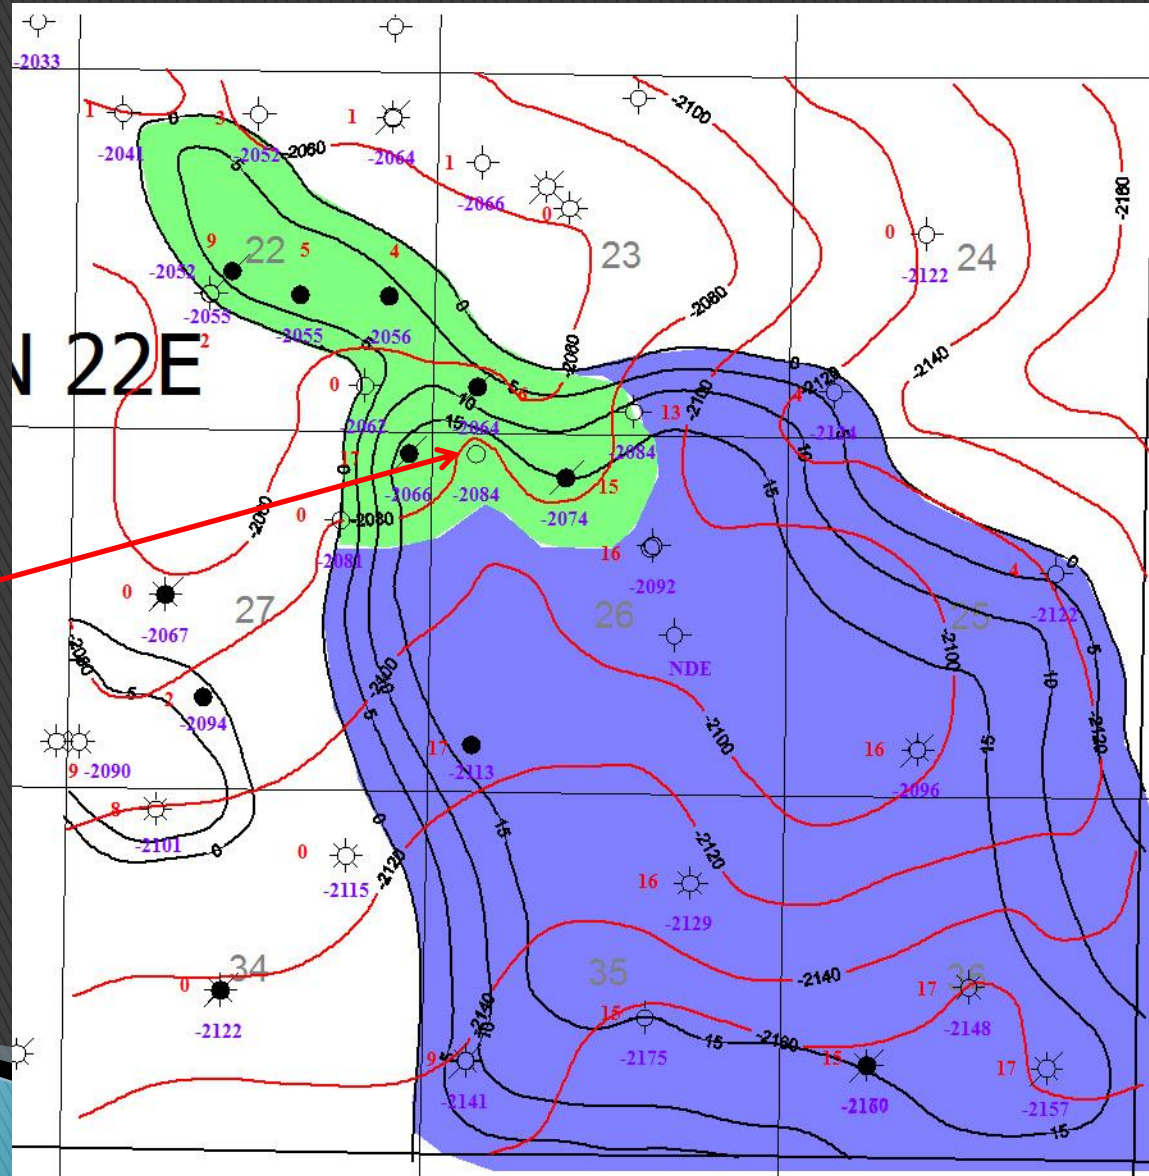

“Brett”–isms

- ▶ The Petrophysical (engineering) parameters matter! Use them and never ignore them.
- ▶ The permeability vs. porosity relationships should always be considered.
- ▶ If the permeability is relatively low vs. porosity, look downdip of an oil show.
- ▶ If the permeability is relatively high vs. porosity, look updip of an oil show.
- ▶ Buoyancy pressure matters! Capillary pressure matters! They offer valuable clues to finding traps.
