Abstract

The Papuan Fold Belt (PFB) exploration took off in 1986 with the Kutubu and immediately after with the Hides discoveries. About 7bboe later, it continues to deliver today with the Muruk discovery. Exploration has advanced on the back of extraordinary surface-related challenges, with an almost exclusively helicopter-supported operation. Mapping using remote sensing images calibrated by field geological campaigns and, to some extent, sparse 2D seismic data, delineated the first drilling targets. Surface information is hindered by topography, thick forest and heavy precipitation, making it difficult to access. Seismic data in the fold belt continues to deliver mixed results in terms of subsurface imaging, which translates to problematic identification of subsurface traps. The PFB depicts thin-skinned, thick-skinned and combined thick/thin-skinned related structural geometries generated by multiple detachments. The stratigraphic pile behaves mostly as a harmonic mechanical beam, but recent discoveries and appraisal/development wells indicate strain partitioning occurs particularly at the Ieru Formation level. The implication of the latter is that in some instances surface structures do not directly relate to subsurface structural culminations. Furthermore, the linkage – geometric and kinematic – between the thick-skinned and thin-skinned structures continues to be an evolving matter of discussion amongst specialists. The kinematic story is faced with an additional obstacle: synkinematic sediments are rarely preserved in the fold belt. This discussion would be of academic interest if not for the fact that surface anticlines that involve our target reservoirs are being drilled-out and we are faced with finding hydrocarbons in deeper structural targets. We are relying on these deep targets to be the new frontier – not to mention the hinterland. Our more complex structures near or along the trend of a developed resource are ever more challenged in terms of defining them with our current seismic data and thus fall in the realm of “sound” structural interpretations or models. A compounding issue to the challenges previously mentioned relates to the economic viability of the discovered resource. There are two main drivers here: gas for LNG; and the geologic (and geographic) extent of the liquids “play” as it relates to existing facilities. There is a large uncertainty related to geological controls that yield gas-rich versus liquid-rich traps. This is where testing the thermo-kinematic history of our models and interpretations can provide insight into the controls of the hydrocarbon phase. Additionally, we could test alternate kinematic models, synkinematic/erosional models and these could be calibrated to known discoveries. This presentation will illustrate, via calibrated and uncalibrated 2D case studies, the effect of structural evolution on maturation, charge and hydrocarbon phase in the PFB.

Beyond Geometry: 2D Structural Thermo-Kinematic Models of the Papuan Fold and Thrust Belt

Disclaimer

While every effort is made to provide accurate and complete information, Oil Search Limited does not warrant that the information in this presentation is free from errors or omissions or is suitable for its intended use. Statements of fact, interpretations and opinions expressed in this presentation are those of Oil Search's Chief Geoscientist and collaborators alone. Subject to any terms implied by law which cannot be excluded, Oil Search Limited accepts no responsibility for any loss, damage, cost or expense (whether direct or indirect) incurred by you as a result of any error, omission or misrepresentation in information in this presentation. All information in this presentation is subject to change without notice.

This presentation also contains forward-looking statements which are subject to particular risks associated with the oil and gas industry. Oil Search Limited believes there are reasonable grounds for the expectations on which the statements are based. However actual outcomes could differ materially due to a range of factors including oil and gas prices, demand for oil, currency fluctuations, drilling results, field performance, the timing of well work-overs and field development, reserves depletion, progress on gas commercialisation and fiscal and other government issues and approvals.

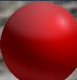

Most Toro-Play surface anticlines and in commercial fairway have been drilled. *Its only getting technically more challenging...*

Trap definition continues to be a major risk. Seismic imaging has improved-*mostly*- but our petroleum systems knowledge is all but stalled. *The latter constrains us to remain in the world of what we 'know', 'don't know' or 'don't care to know'*

Deeper targets conceived using seismic data- *near our producing assets*- can be 'pre-tested' for charge and phase. *Q: will we be able to hook up a particular potential resource to deliver the \$?*

There are relatively low cost propositions that could advance our understanding of the PNGFB Petroleum System *and thus enable us to optimize our exploration Portfolio*

PART 1.

Bad News: It is more complicated than just geometry

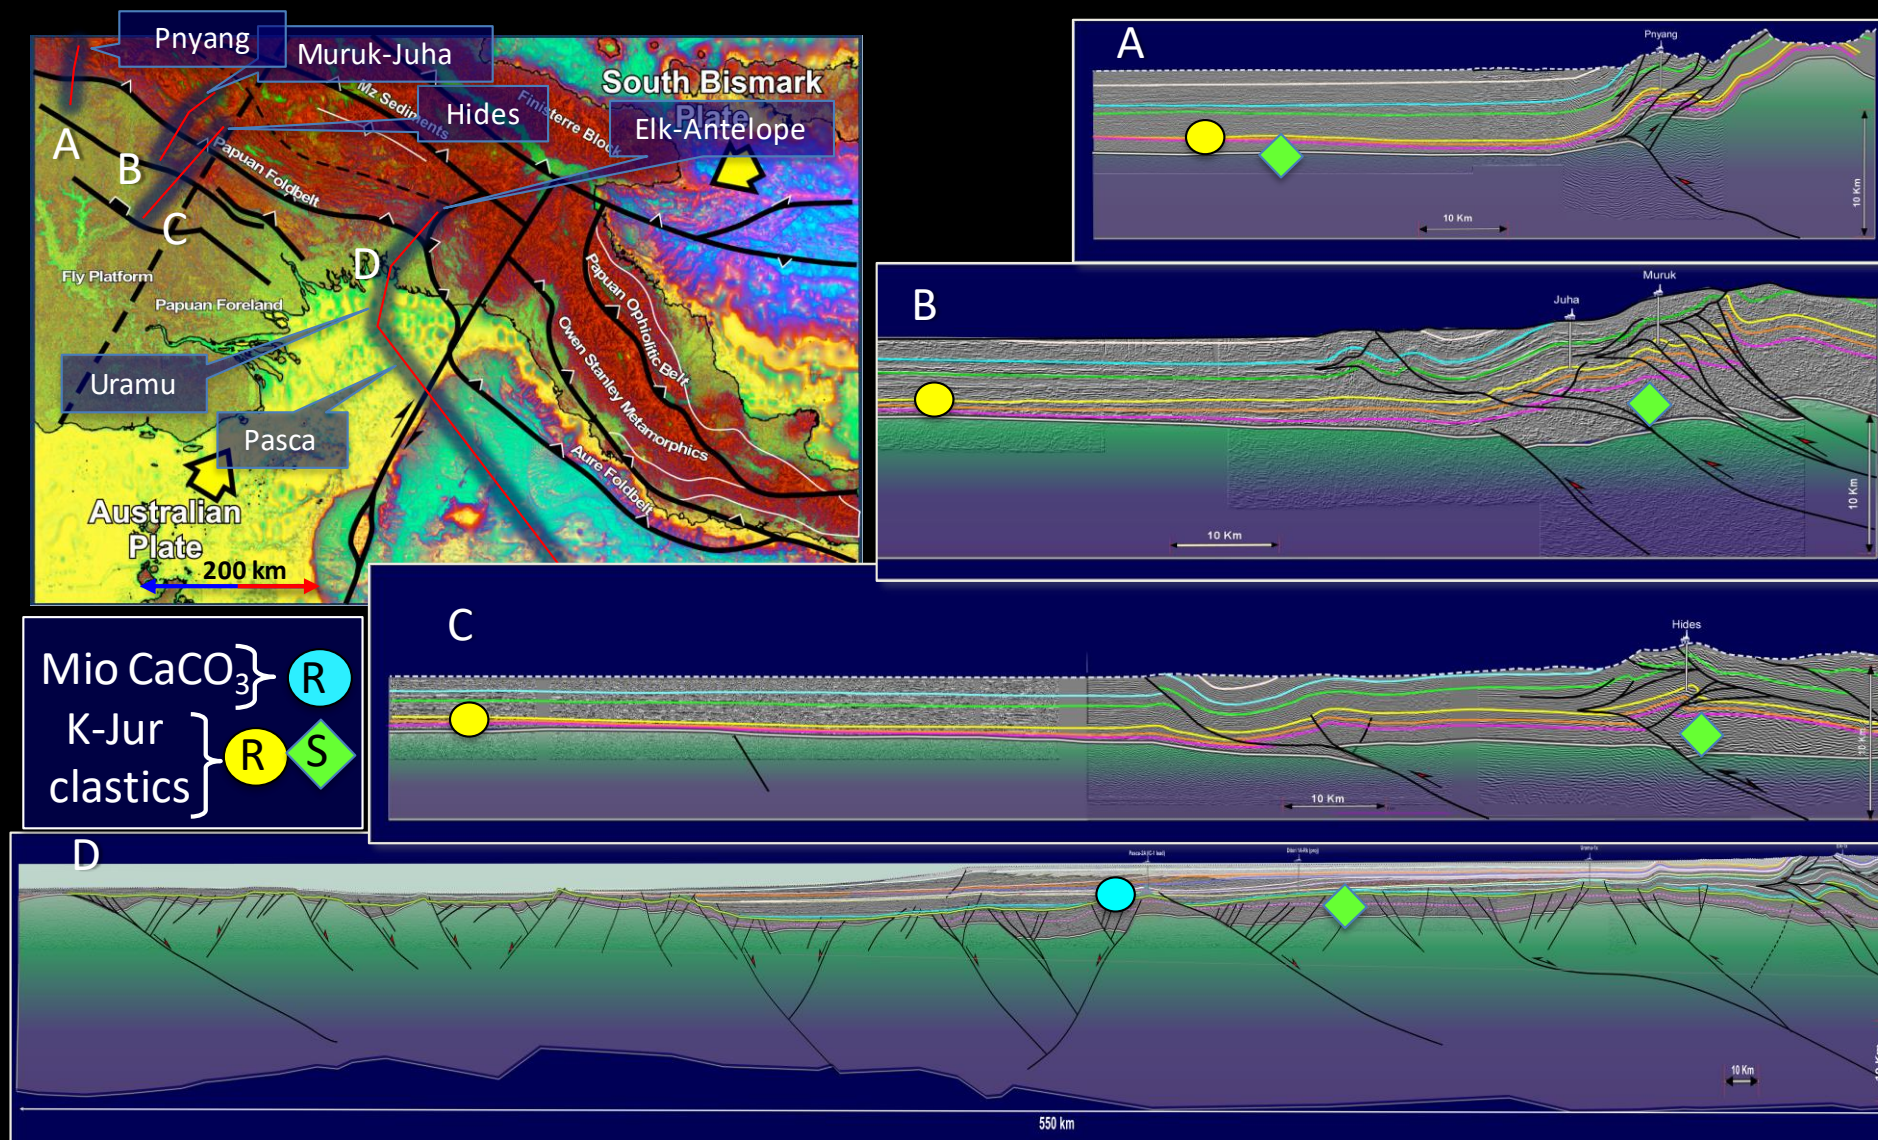

Example 1. HC phase as a function of thrust timing

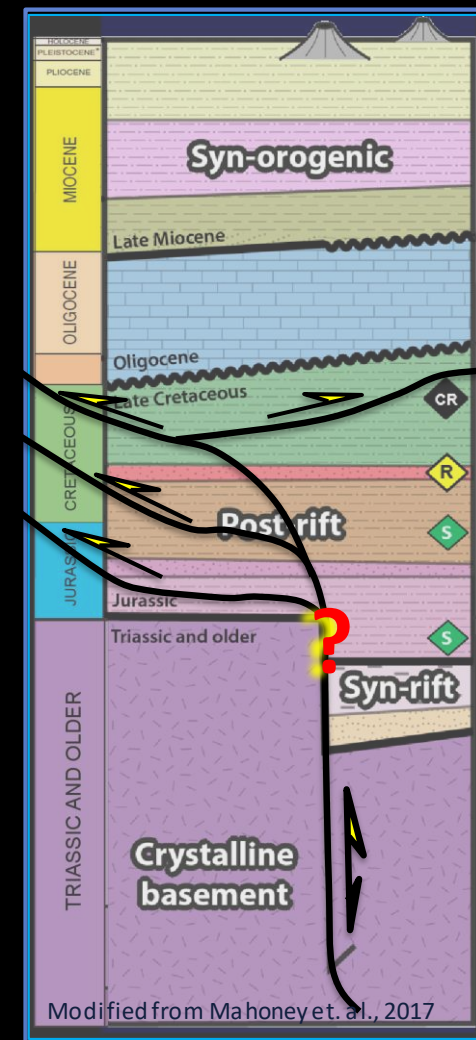

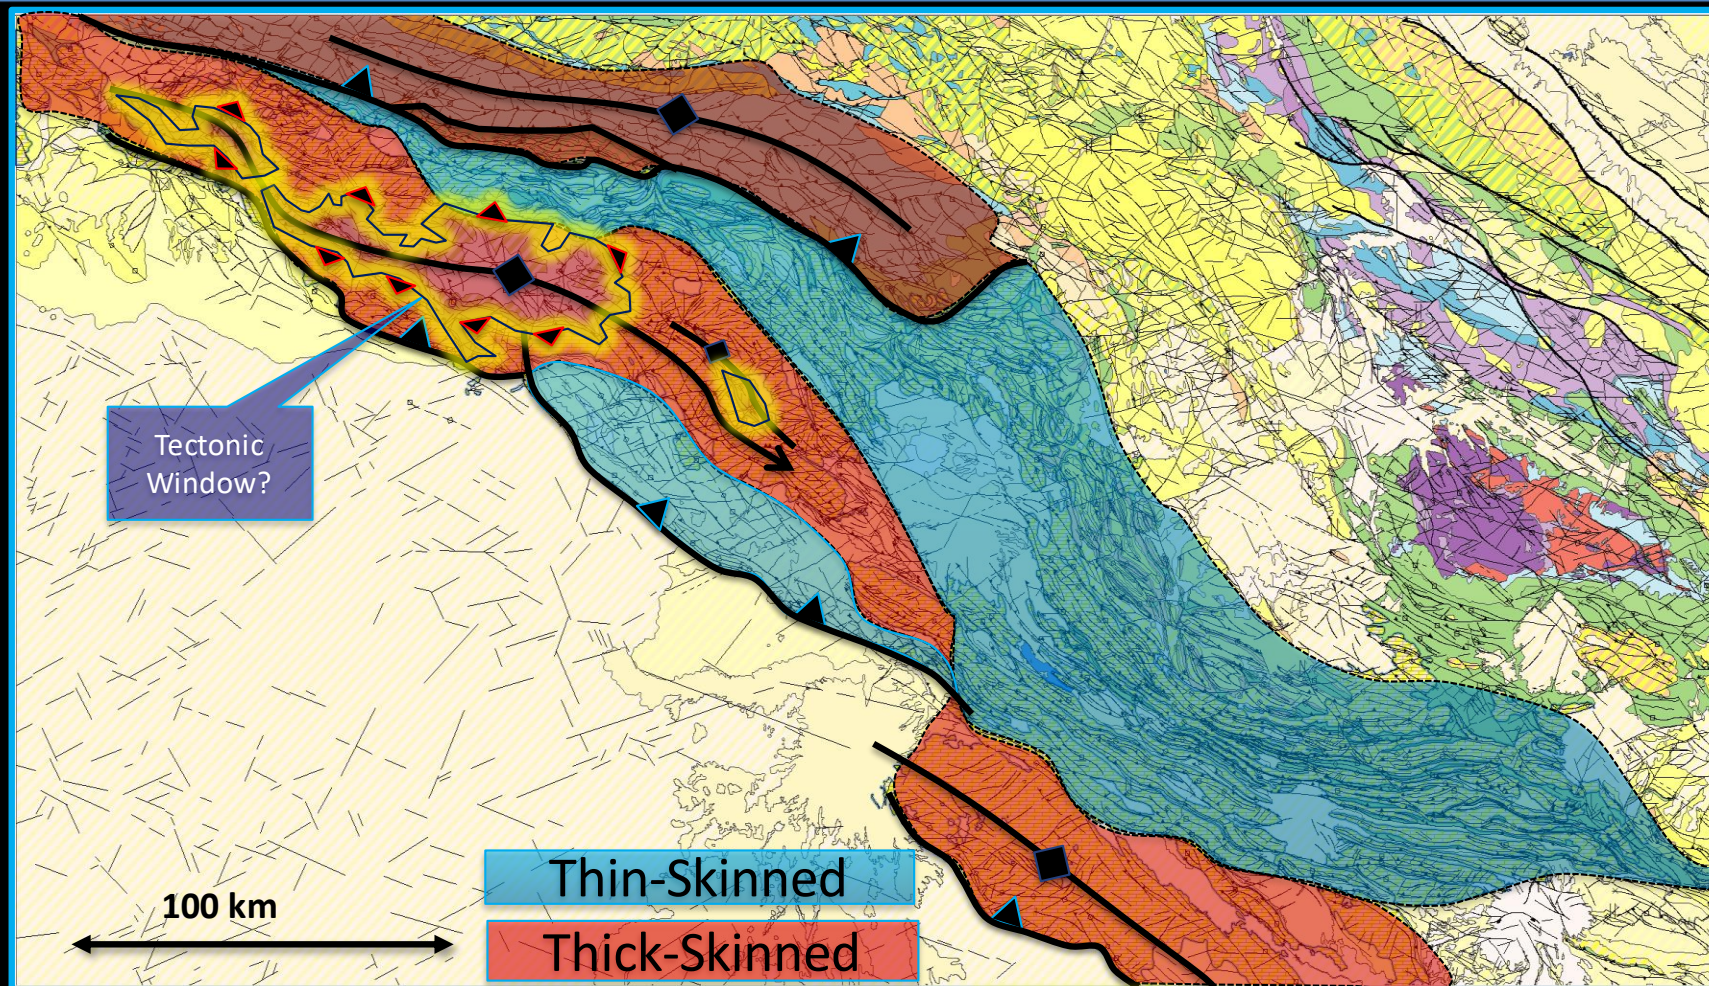

Example 2. Charge of deeper targets under lean or rich conditions

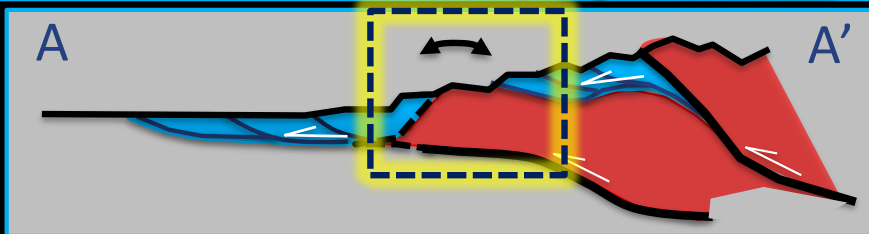

PART 2.

Good News: we can improve on our predictions by applying adequate modelling tools and gathering data to constrain such models, at relatively low cost

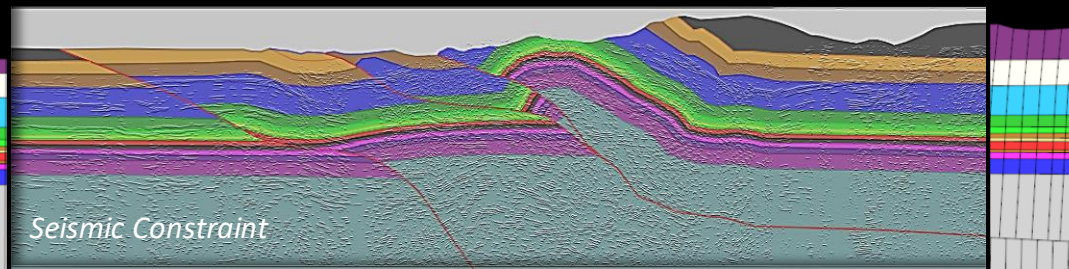

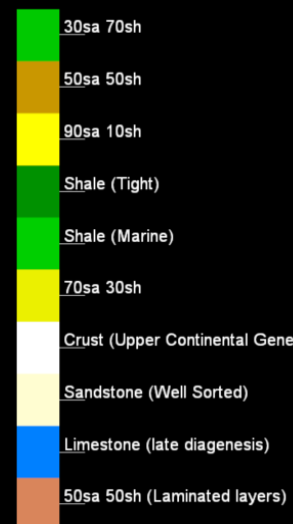

Kinematics: relevant to our de-risking?

- Deeper and more complex structural targets are becoming more challenging to define and drill.
 - Exploration is largely tied to add resources to declining fields and to fill existing pipelines. The latter constraining the exploration fairway.
 - Standalone Exploration targets require multi MMbo or multi Tcf to be viable
- Therefore, the evaluation of our structural targets require more holistic de-risking methods; one that places our structural interpretation in a Petroleum System Context
- OSL has implemented thermo-kinematic (Kronos) modelling as a routine de-risking workflow. In order to constrain these models, we are re-initiating a campaign of targeted data acquisition in the field and from well samples e.g. rock-fluid Geochem and low-temperature geochronology...
