Abstract/Excerpt

The Guyana-Suriname Basin is a half graben Atlantic-margin basin on the northeast coast of South America (Figure 1). It was rated as the second most prospective unexplored basin in the world according to the USGS in its World Petroleum Assessment 2000. World class Canje source beds are in a mature position (Figure 2). The main reservoir targets are Upper Cretaceous and Lower Tertiary basin floor fans, shelf-margin deposits and turbidites directly overlying mature source. Recent seismic combined with 1970's well control provides an exploration framework. Depth mapping of deep closures have eliminated the distortion/velocity pull-up by an overlying shelf margin carbonate bank of Tertiary age. Large closures have been mapped and are associated with significant shows from 1975 drilling.
