Abstract

Tellurian is developing a globally integrated gas business with additional production from the Haynesville Shale as a key component. Development has focused on the eastern fault zone area of the Haynesville Shale. Development relies on several key geologic inputs. Assessment of Haynesville and Bossier shale intervals will allow the industry to develop this area fully. Extensional faulting during Bossier's time affects development and relies on careful integration of well control and 3D seismic data. Accurate well placement assures maximum operational efficiency and economic return. Along with other activity in the Haynesville Basin and other North American basins, this gas can provide an accessible and abundant supply to provide needed energy in a challenging geopolitical environment.
