## **Abstract**

Restimulation of existing wells represents a vast underexploited resource. A successful refracturing treatment is one that creates a fracture having higher fracture conductivity and/or penetrating an area of higher pore pressure than the previous fracture. Re-fracturing requirements are different in highly permeable formations (high fracture conductivity) as compared to low permeable ones (moderate fracture conductivity). Understanding these basic differences is essential to a successful restimulation.

In the past, candidate selection methodology has focused on underperforming wells. This simplistic approach has yielded disappointing results and has led to a common misconception that restimulations “don’t work.” Production statistics of a well alone may not offer an effective methodology for selection of a restimulation candidate. Other parameters such as high BHP (remaining reservoir energy), recoverable reserves, HPV and favorable response to original fracture jobs (IP) could play an equally important role, if not greater, in determining the success of restimulation. In fact, studies have shown that selecting poor or underperforming wells for restimulation is likely to result in worse outcomes than random selection of workover candidates.

Studies performed to date have concluded that no selection criteria can be universally applied to every situation; rather that the selection methodology for workover candidates must be customized to fit particular situations. This paper explores the common traits shared by fields likely to have underexploited restimulation potential and suggests methodologies that should be applied to various field types. Application of the correct candidate-selection methodology to a particular field type will inevitably lead to a higher success rate of restimulation workovers and the capture of an underexploited resource.

# Restimulation – Presentation Outline

The background of the slide features a light blue, semi-transparent image of a beach. In the foreground, gentle waves are washing onto a sandy shore. In the distance, a tall, modern building is visible, its form reflected in the water. The overall aesthetic is clean and professional.

- History of restimulation
- Common traits of areas with restimulation potential
- Case histories
- Selection methodology
- Conclusions

# Prevailing Attitudes Towards Restimulation – GRI Survey

- “Cannot be economically justified”
- “We’ve had bad experiences with refracs”
- “It’s better to abandon the well”
- Restimulations < 3% of total treatments

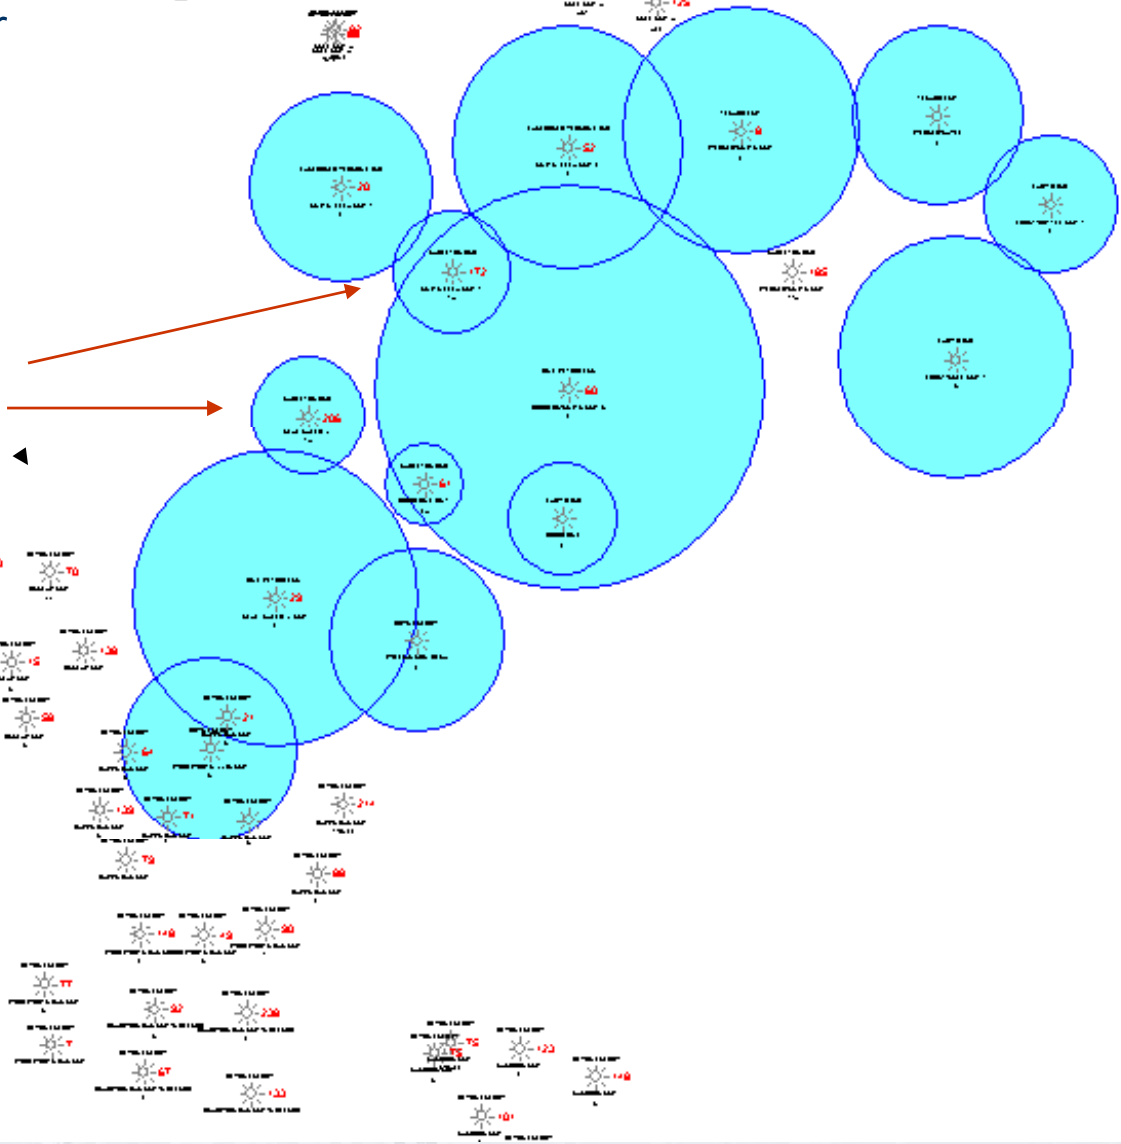

# GRI Study - Selection Methodology

The background of the slide features a faded, light blue image of an offshore oil rig on the water. The rig is a large, complex structure with multiple towers and platforms, situated in the distance. The water in the foreground shows gentle ripples, and the overall scene is presented in a monochromatic, light blue color scheme.

Concluded that selecting wells on underperformance alone was substantially less likely to yield successful candidates than random selection in a heterogeneous reservoir

# Heterogeneous Reservoir

Poor Restim  
Candidates

# Restimulation 2008

- Operators universally interested in restimulation because of high product prices
- Many operators are dedicating personnel to identifying candidates
- Some areas seeing a significant upward trend in restimulation activity

# Common Traits of Areas with Restimulation Potential

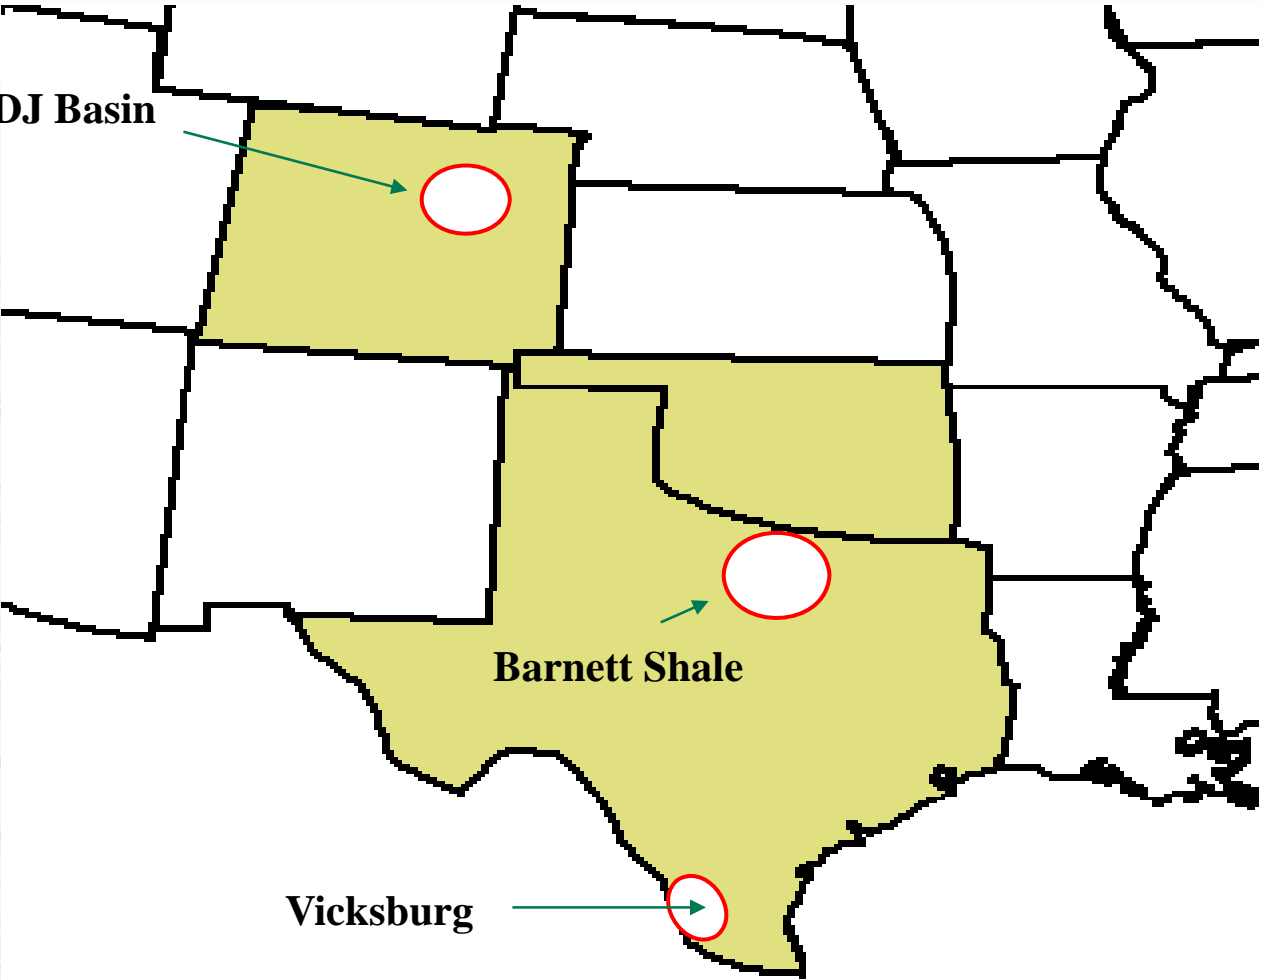

1. Complex reservoirs with problematic initial completions
2. Plays with important technological improvements
3. Older wells that have suffered damage during production
4. Plays with multiple producing horizons that may have been stimulated with limited entry techniques

# Case Studies

Codell DJ Basin

Barnett Shale

Vicksburg

# Case Number 1 – Barnett Shale

# Barnett Shale

Common Traits 1 and 2– complex reservoir, technology evolution

- Candidate selection – better performers with 2 to 5 years of production history
- Much of Ft. Worth basin has low stress anisotropy
- Increased drainage area through fracture reorientation
- Water fracs replacing gel fracs
- Bigger secondary frac
- Some “restimulations” also adding new zones

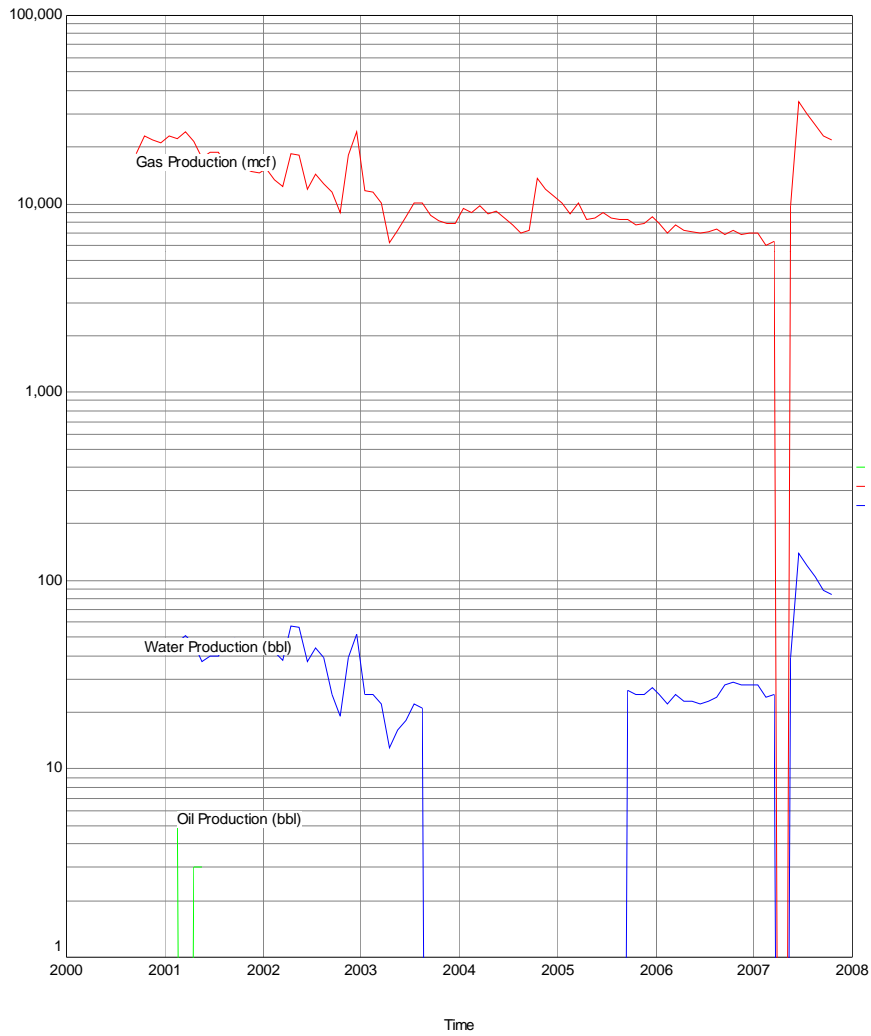

# Re-frac Re-orientation Concept

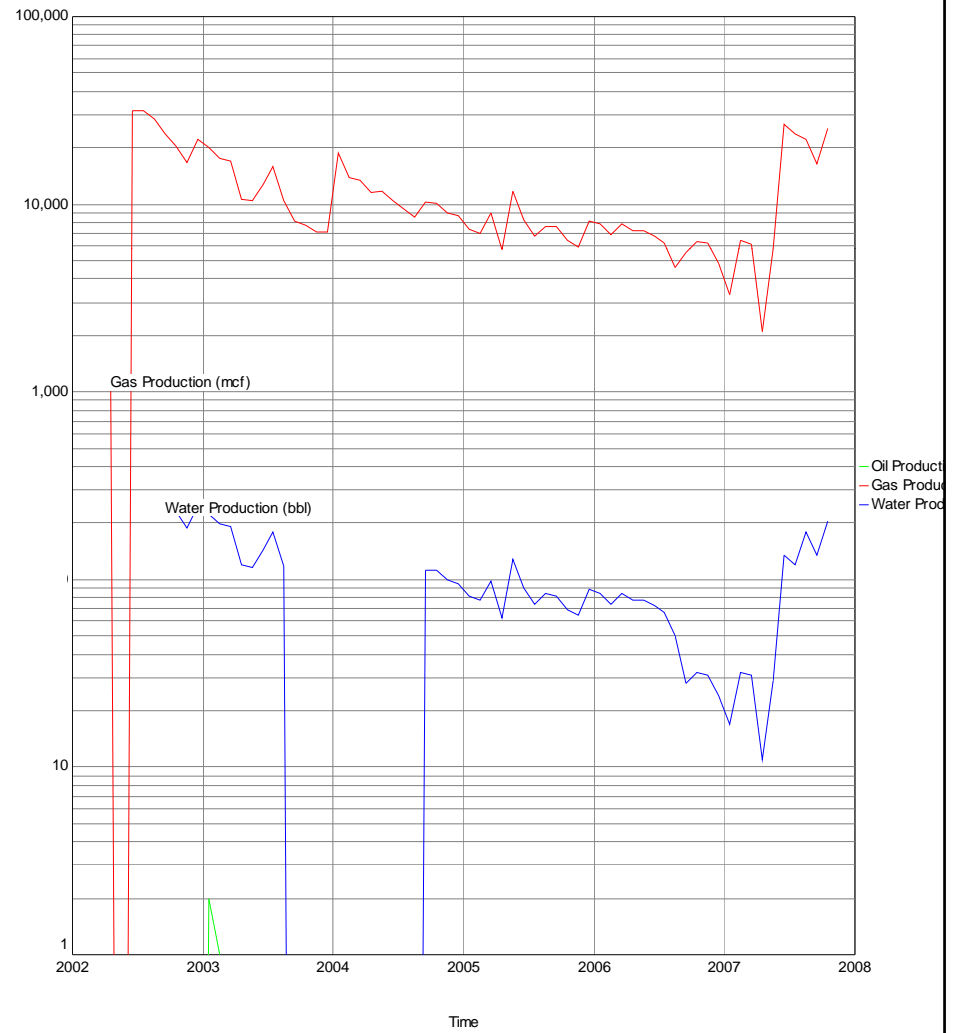

**Re-orientation propensity dependent on stress anisotropy**

# Barnett Shale Restimulation

ELKINS UNIT - NEWARK EAST

ELKINS UNIT - NEWARK EAST

# Case Number 2 - Vicksburg

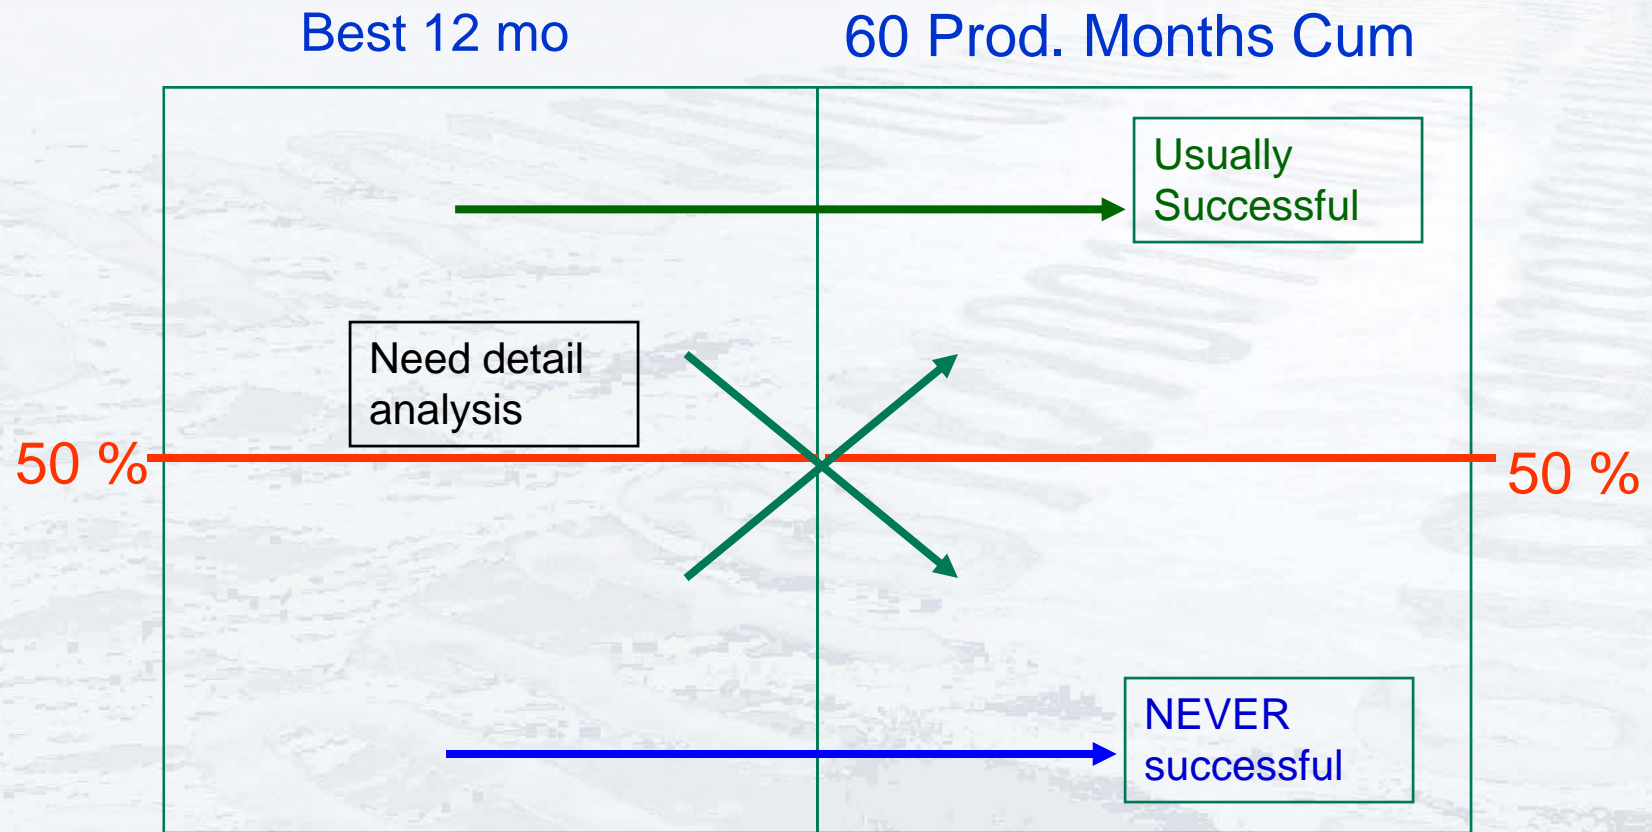

# Vicksburg – South Texas

Common Traits 1, 2, and 4 – complex, technology evolution,  
multiple zones

- Original completions in 70's and 80's
- Very low matrix permeability: .005 to .1 md
- Multiple zones; some limited entry
- Success rate > 80%
- Key to success: highly customized selection methodology

# Candidate Indicator: Quadrant Movement

# Vicksburg Selection Methodology

<b><i>Candidate Indicator</i></b>	<b>Well #1</b>	<b>Well #2</b>	<b>Well #3</b>
<b>Gas Best 12</b>	<b>3</b>	<b>3</b>	<b>5</b>
<b>60 Productive Months Cum</b>	<b>2</b>	<b>1</b>	<b>5</b>
<b>(Ranking for workover review &amp; pre-production trend analysis)</b>	<b>5</b>	<b>4</b>	<b>10</b>
<b>Water prod. vs. Gas prod ratio</b>	<b>4</b>	<b>2</b>	<b>5</b>
<b>Gas Decline Trend</b>	<b>4</b>	<b>3</b>	<b>5</b>
<b><u>**Proppant type &amp; amount</u></b>	<b>1</b>	<b>1</b>	<b>4</b>
<b>(Ranking for production modelling, economic analysis, pressure survey)</b>	<b>14</b>	<b>10</b>	<b>24</b>

# Case Number 3 – Codell DJ Basin

# Codell DJ Basin located on the plains east of the Rocky Mountains

DJ Basin

Low Stress Anisotropy

# Codell DJ Basin

Common Traits 1 and 2 – complex reservoir, technology evolution

- Low perm, naturally fractured, non-competitive SS reservoir
- Using better frac fluids and evolved stimulation techniques, created fractures 300' to 400' longer
- Real time frac supervision kept frac in zone
- Fracture reorientation is believed to an important component – many wells restimulated twice

# Generalized Selection Methodology

1. Literature Review
2. Scoping Study
3. Performance Based Screening
4. Well data review
5. Identification of key drivers and indicators
6. Integrated evaluation of best candidate wells
7. Restimulation of best candidate wells
8. Evaluation of results and revision of selection criteria

# Scoping Study

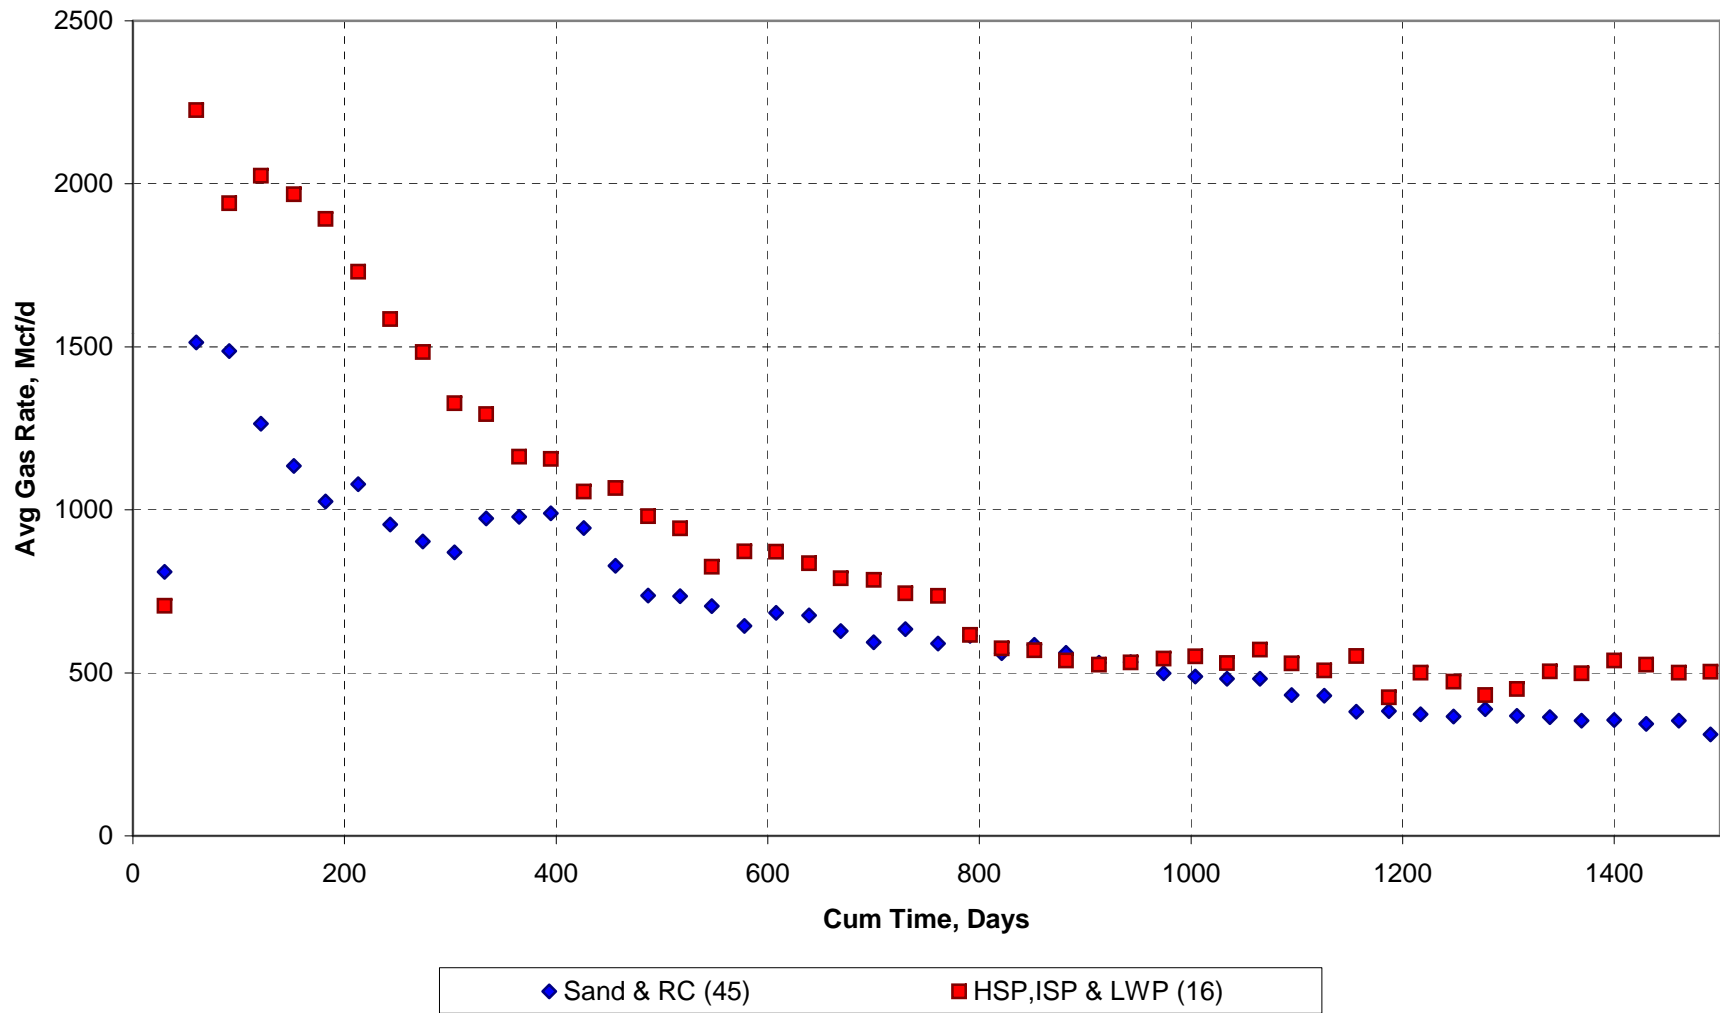

## •Parameters Available in Public Domain

- Production
- Frac fluid volume and type
- Proppant volume and type
- Perforated interval
- Operator
- DOFP
- Pressure
- Well density

# Completion Data Analysis

## Average Gas Rate vs. Cum Days by Proppant Type

# Production Indicators and Stimulation Type

# Conclusions

- Areas ripe for restimulation have one or more traits in common
- Selection methodology must be customized to fit the particular needs of a given field
- Substantial incremental reserves can be added if the correct candidate selection process is followed
