## **Abstract**

Seven wells (five in Tarrant County, one in Johnson County, one in Bosque County), covering approximately 100 km along the NNE-SSW trend of the axis of the Fort Worth Basin (Texas, USA), were selected for the measurement of total organic carbon (TOC) as well as organic carbon isotope ratio ( $\delta^{13}\text{C}_{\text{org}}$ ) of the Mississippian Barnett Shale. The TOC and  $\delta^{13}\text{C}_{\text{org}}$  value of 98 rock cuttings from 7 wells ranges from 1.3 to 6.2%, and -23.9 to -29.7‰ (means -27.4‰), respectively. If we assume  $\delta^{13}\text{C}_{\text{org}}$  value of two end members, i.e. marine and continental organic matter, to be -22 and -30‰, respectively, our study indicates the dominance of continental type organic matter within the study area of the basin.

The systematic variation of TOC and  $\delta^{13}\text{C}_{\text{org}}$  of each well reveals that the Barnett Shale is characterized by three major cycles. Each cycle is characterized by inverse correlation between TOC and  $\delta^{13}\text{C}_{\text{org}}$ . The trend of decreasing or increasing continental-type organic matter (increasing or decreasing value of  $\delta^{13}\text{C}_{\text{org}}$ ) with decreasing or increasing TOC is unusual (Creaney and Passey, 1993). The TOC and  $\delta^{13}\text{C}_{\text{org}}$  cycles can be correlated with the 3<sup>rd</sup> order global sea level curve. The study suggests that each sea level rise was tied with decreasing value of  $\delta^{13}\text{C}_{\text{org}}$  and increasing value of TOC. The sea level rise within the basin may be due to positive water balance with an excess outflow of relatively low salinity surface water, which inhibited the haline circulation of the basin and made it more anoxic (e.g. present day Black Sea). The basin anoxia condition might have resulted from basin restriction due to increased tectonic activity along the Ouachita thrust (this time was characterized by increased tectonic activity along the Ouachita thrust due to the approach of the Laurentia towards Gondwana). On the other hand, the sea level rise as a result of deglaciation due to increased  $\text{pCO}_2$  level, caused more input of continental type organic matter within the basin. The positive correlation between TOC and phosphate content along the depth profile from one well confirms this argument (more nutrient supply during sea level rise). Both  $\text{pCO}_2$  rise and basin anoxia

together increased the preservation possibility of continental type organic matter. Therefore, the TOC and  $\delta^{13}\text{C}_{\text{org}}$  cycles within the Barnett Shale were the results of complex interplay among  $\text{pCO}_2$ , basin anoxia and tectonic activities.

# Principles

$\delta^{13}\text{C}_{\text{Org}} (\text{‰})$

C3 plant

**$\sim(-28)$**

C4 plant

**$(-10) - (-14)$**

Continental

Marine

phytoplankton

**$\sim(-21)$**

$$\delta^{13}\text{C} = \left[ \frac{(^{13}\text{C}/^{12}\text{C})_{\text{sample}}}{(^{13}\text{C}/^{12}\text{C})_{\text{standard}}} - 1 \right] \times 1000$$

Produces continental  $\delta^{13}\text{C}_{\text{Org}} (\text{‰}) \sim -28$

Continental Plant

Use atmospheric  $\text{CO}_2$   
whose  $\delta^{13}\text{C} \sim (-7)$ , for  
photosynthesis

Fractionation between organic and  
inorganic carbon  $\Delta^{13}\text{C}_{(\text{Inorganic-organic})} \sim 21$

Marine  
phytoplankton

Use water dissolved  
 $(\text{HCO}_3)^-$  whose  $\delta^{13}\text{C} \sim 0$ , for  
photosynthesis

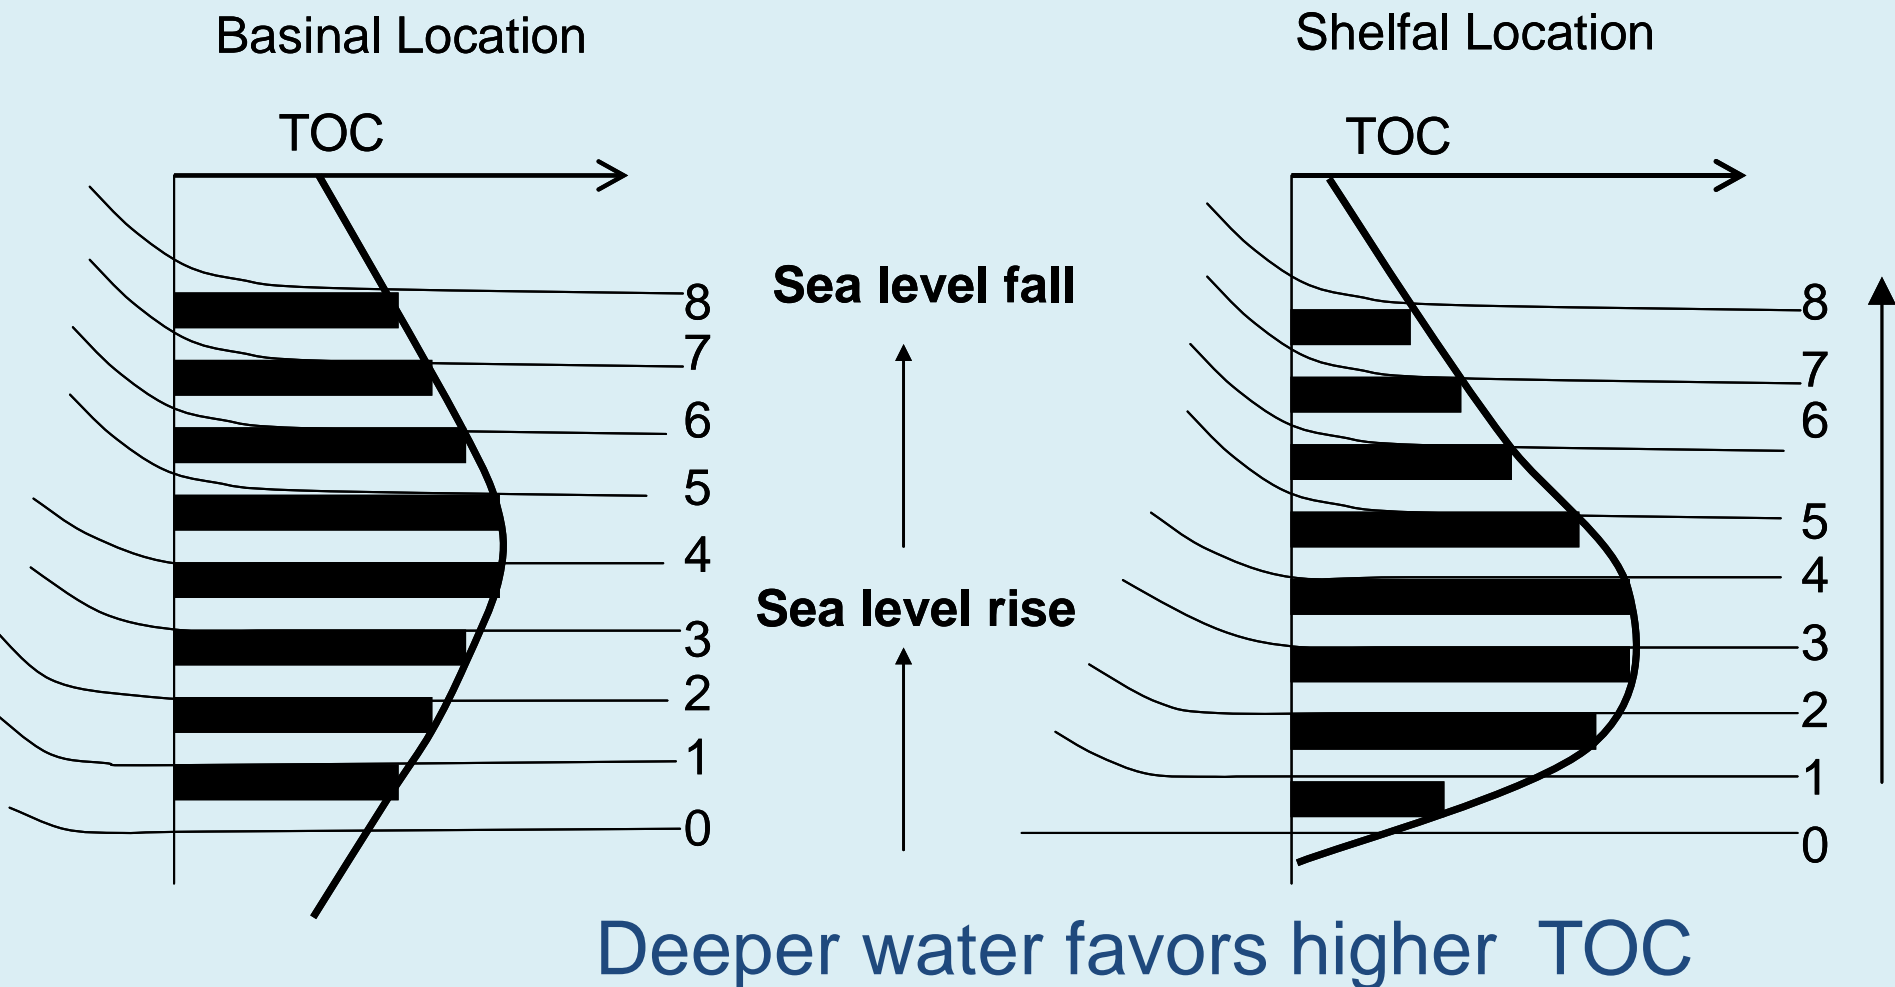

Produces marine  $\delta^{13}\text{C}_{\text{Org}} (\text{‰}) \sim -21$

The correlation of the Barnett Formation within different wells. The correlation was done on the basis of already established cycles.

The diagram exhibits the antithetic relation between TOC and  $\delta^{13}\text{C}_{\text{org}}$  of the Barnett Formation from seven wells

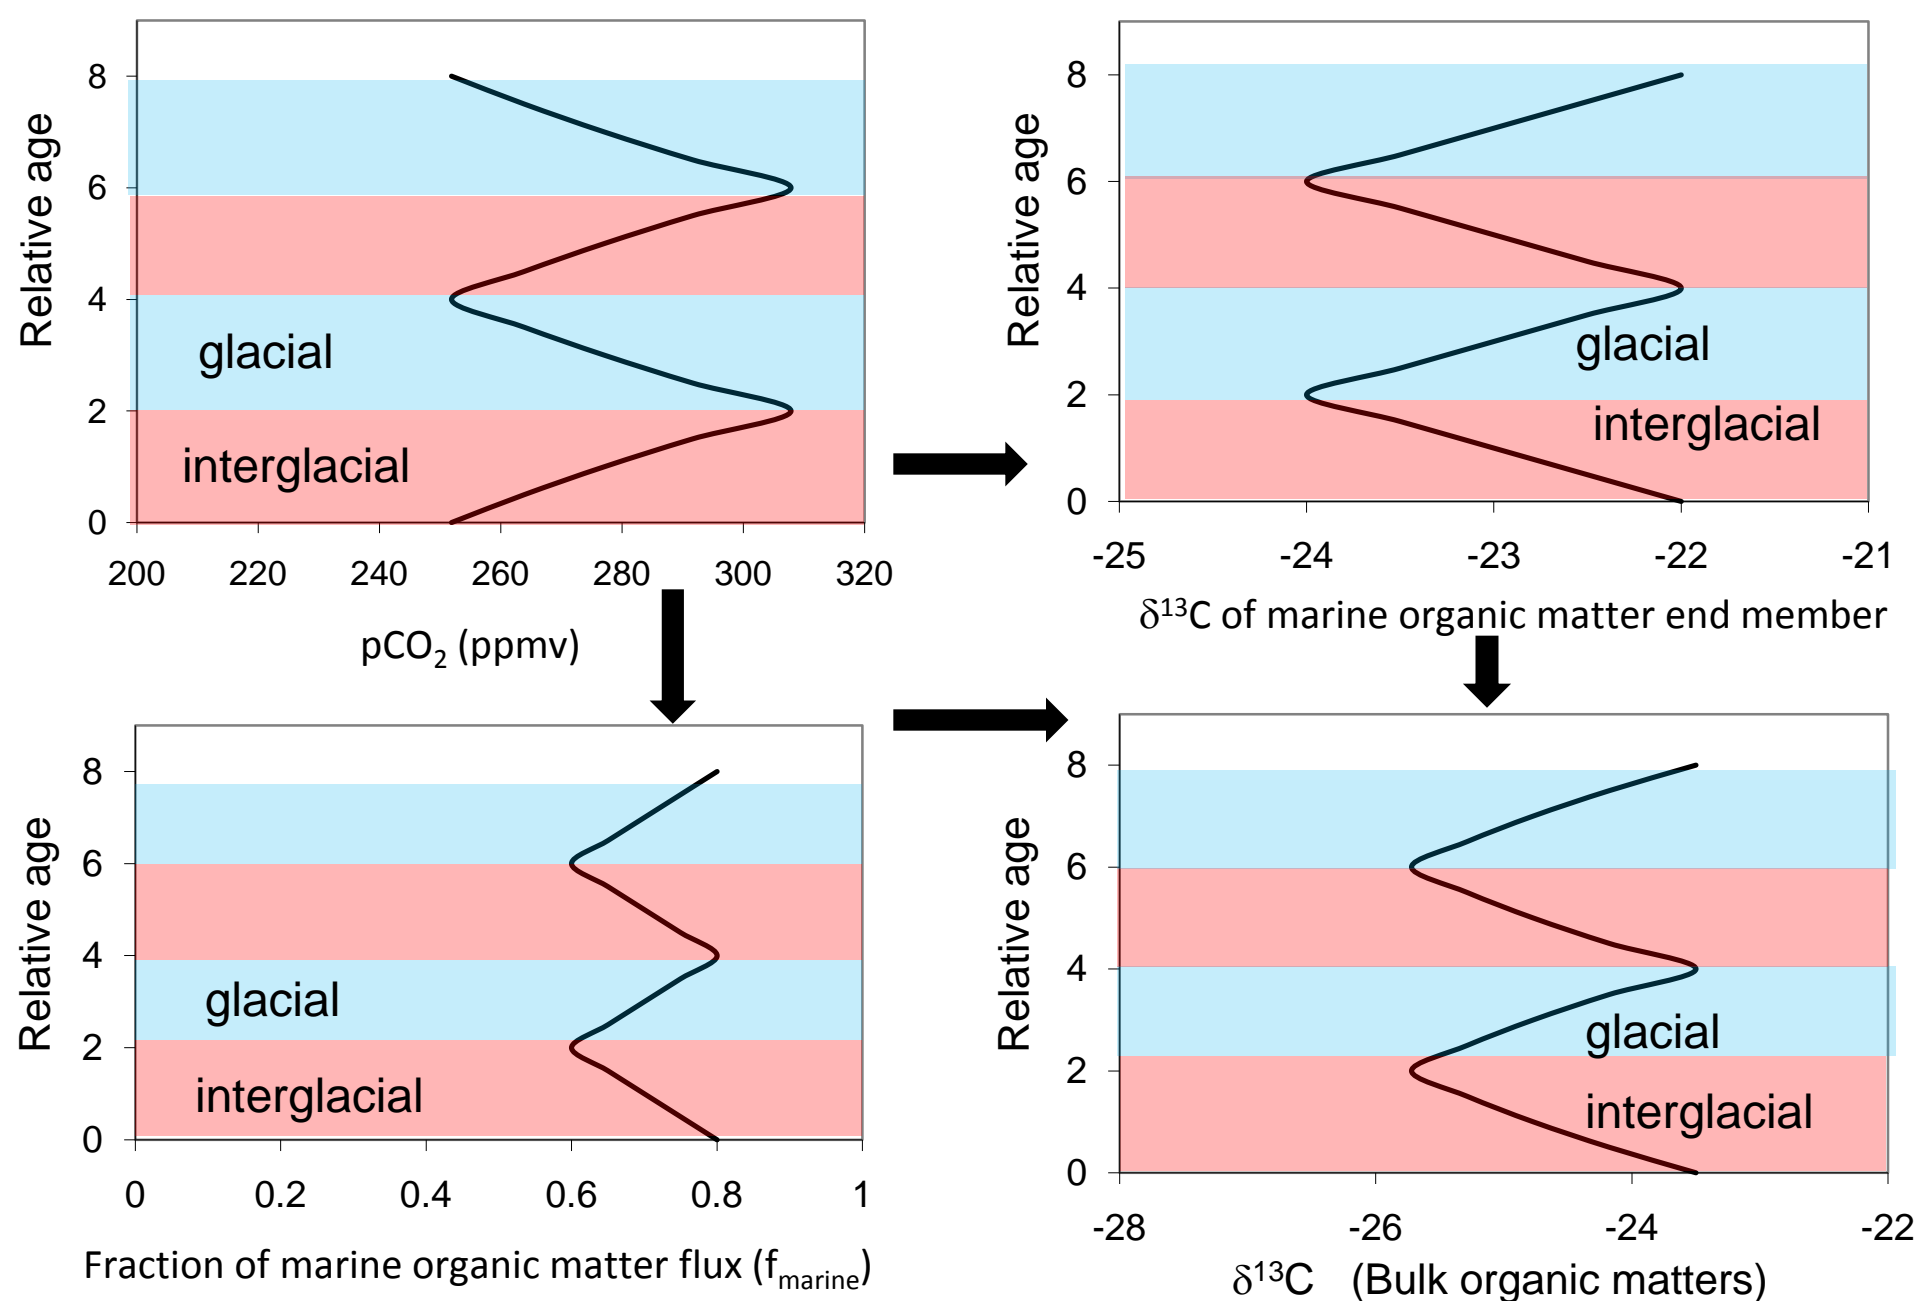

## Relation between $\delta^{13}\text{C}$ and $\text{pCO}_2$

$$\delta^{13}\text{C}(\text{org}) - \delta^{13}\text{C}(\text{carb}) = \left[ \frac{(159.5 [\text{PO}_4]) + 38.99}{(0.034 \text{ pCO}_2)} \right] - 33$$

Assuming constant  $\delta^{13}\text{C}(\text{carb}) \sim 0$

(Kump and Arthur; 1999)

Model constraints: (1) Constant  $\delta^{13}\text{C}$  of continental organic end member value.  
(2) Constant phosphate concentration in the basin.

The diagram exhibits an overall similarity between 3rd order sea level change curve and  $\delta^{13}\text{C}_{\text{org}}$  profile of the Barnett Formation.

## Modern analogues

3,000 years ago

7,000 years ago

11,000 years ago

22,000 years ago

## Eastern Mediterranean Sea

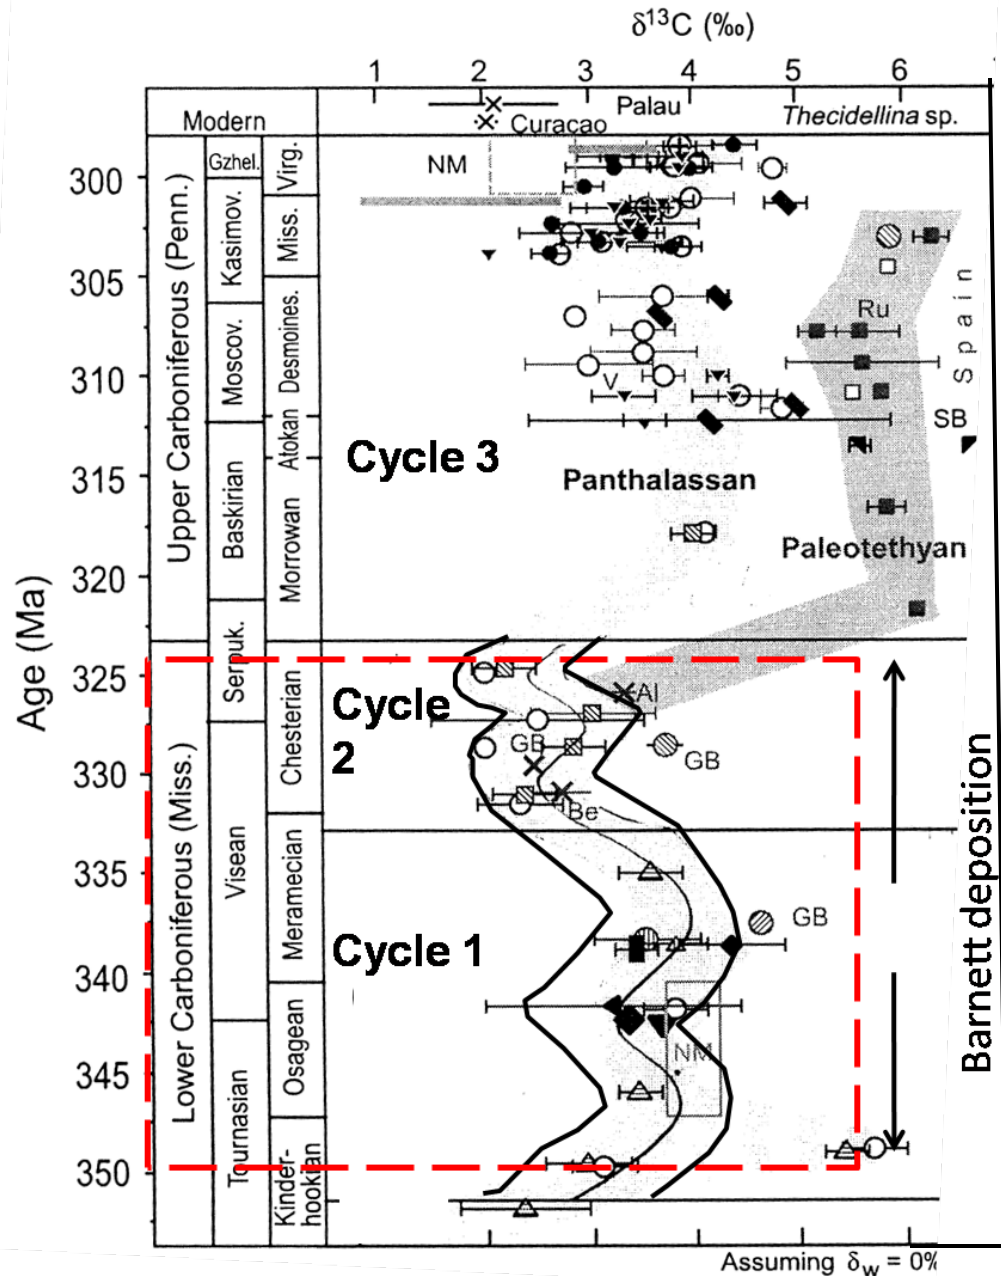

Intermittent anoxic condition prevailed 5 times during last 9000 years due to large and sudden influxes of fresh water from ice melting or precipitation

(Demaison and Moore, 1978)

# Carbon isotope records of carbonates from North America

Carbon isotope data from North American Brachiopod shells also exhibit similar type of cyclicity during the Missippian.

(Mii et al, 1999)

## Conclusions:

- Carbon isotope ratio of bulk organic matter from the Barnett Formation documented the paleoclimatic signature of the Mississippian.
- Our study reveals 3<sup>rd</sup> order sea level change during the Barnett formation.
- $\delta^{13}\text{C}_{\text{org}}$  and TOC can be used as geochemical correlation tool within organic rich shale/mudstone.
