Abstract

In Unconventional Resources (Shale Gas, Tight Gas, and Coal Bed Methane), the hydrocarbon system elements (source, reservoir, seal, hydrocarbon recovery, etc.) are controlled by the properties of a single lithology or closely spaced groups of lithologies. The ability to commercially extract natural gas from Unconventional Resources represents the primary risk in these resource types, and the commerciality of a particular play varies spatially within the region of hydrocarbon occurrence. Therefore, it is critical to identify and evaluate the commerciality of Play Fairways (aka Sweet Spots) and differentiate these fairways from non-commercial areas.

Although the properties of a single lithology can control Unconventional Resource commerciality, the properties of that single lithology represent the complex interaction of sedimentation and basin/tectonic evolution. In addition, Unconventional Resources require artificial stimulation (generally hydraulically induced fractures) in order to produce gas at commercial rates. Understanding/predicting commerciality in Unconventional Resources therefore requires understanding of a complex natural system and how that system will respond to engineering intervention.

In comparison to the complexity of the system, geoscientists generally have little data of sufficient quality to apply machine-learning techniques. Expert systems such as Bayesian Belief Networks (BBN) are being used successfully to evaluate Unconventional Resources. BBNs are used: 1) to break the complex system into smaller, tractable pieces; 2) as a flexible tool to incorporate beliefs based on theory, empiricism, and tacit expert knowledge; 3) to manage system and input uncertainty; and 4) to improve expert understanding, improve communication, and as a tool to teach new practitioners.

To exploit the power of BBNs as a predictive tool, numerous tools that link BBNs to Geographic Information System (GIS) data have been developed within ExxonMobil. These tools: 1) Allow for output maps to be created based on BBN output and GIS based inputs 2) Visualize probabilistic output. 3) Aggregate probabilistic results to summarize resource estimates for areas of interest. In addition, a GIS enabled database of calibration data has been created that allows for the comparison of BBN predictions to actual results. The expert uses these validation tools to improve predictive ability and gain insight into Unconventional Resources systems.

**Using Bayesian Belief
Networks to Evaluate
Continuous Gas Resources
(Shale Gas, Tight Gas, and
Coal Bed Methane): Tools
to Calibrate the Expert and
Exploit Knowledge.**

Kurt Steffen, PhD

Bayesian Belief Networks (BBNs)

- Uses a Causal Net to quantify relationships.
- BBNs break understanding of the system into small, tractable pieces
- BBNs are very flexible, we can use multiple sources to quantify the relationships as well as calibrate the results
- Acknowledges the multi-variable, complex nature of Unconventional Resources
- Because the process is automated, large numbers of polygons can be run thru the system, approximating the continuous nature of the continuous resource.
- Less sensitive to arbitrary “cut-offs” if well calibrated

Bayesian

A causal Belief Network for the area of a rectangle:

Algebraic	Probabilistic
$Area = Width * Depth$	$p(Area Width,Depth)$

Read as: The Probability of Area given Width and Depth

The algebraic case can easily be handled by multiplication and the probabilistic case could be handled with Monte Carlo Techniques

What if someone asks “If I give you the Area and the Width, can you tell me what the Depth is?”

Algebraic	Probabilistic
$Depth = Area / Width$	$p(Depth Area,Width)$

Bayes’ theorem allows us to calculate $p(Depth|Area,Width)$ using the Belief Network shown above.

Therefore we can build a single causal network that also allows inference of the causes based on knowledge of the effects.

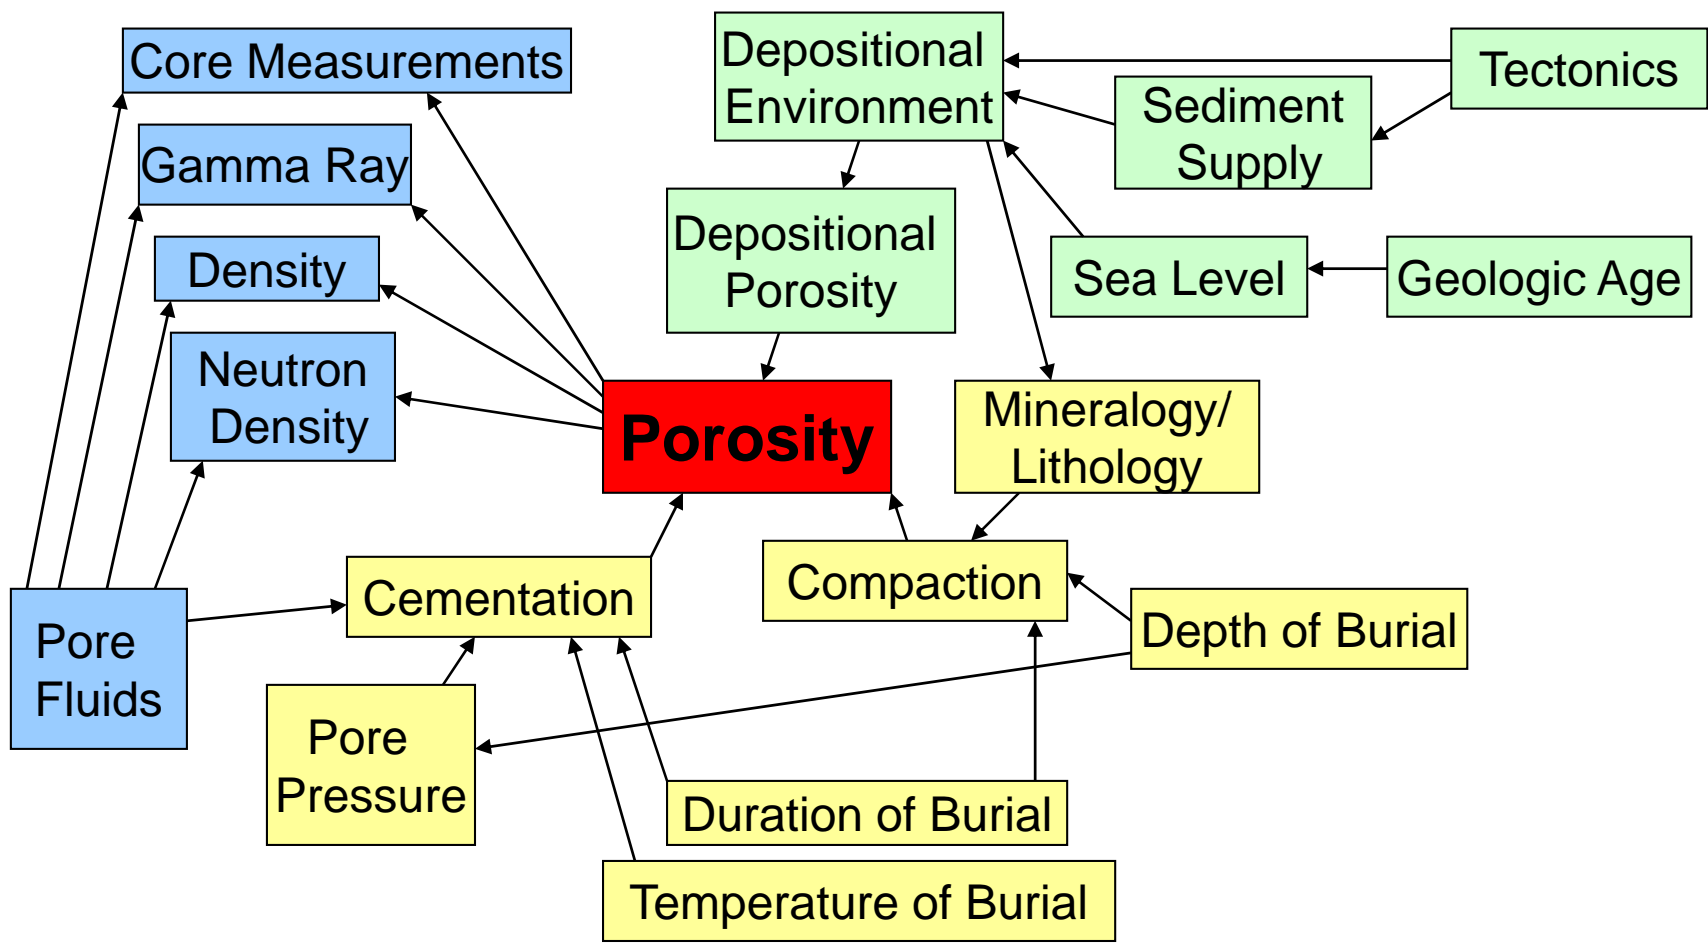

In short we can update our understanding based on adding knowledge about any variable in the network

Thomas Bayes (c. 1702 – [7 April 1761](#)) was a British mathematician and Presbyterian minister, known for having formulated a specific case of the theorem that bears his name: **Bayes' theorem**, which was published posthumously.

Why BBNs for Unconventional Gas Resource Evaluation?

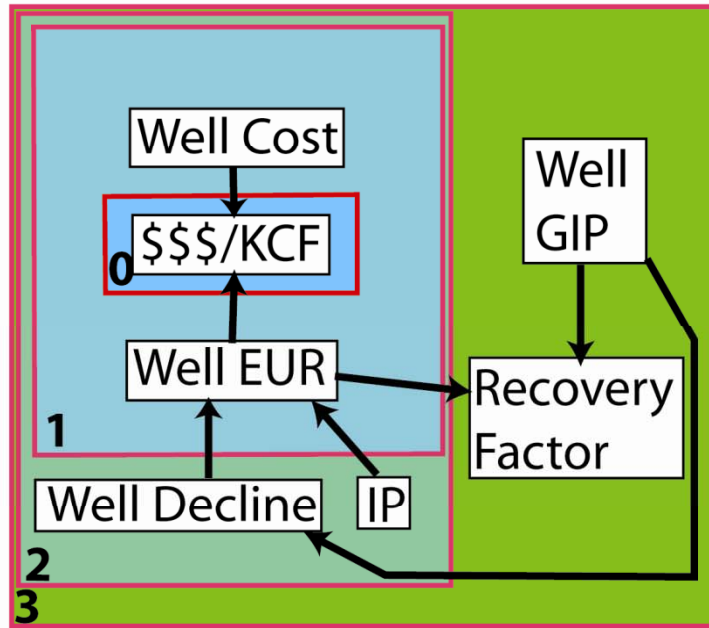

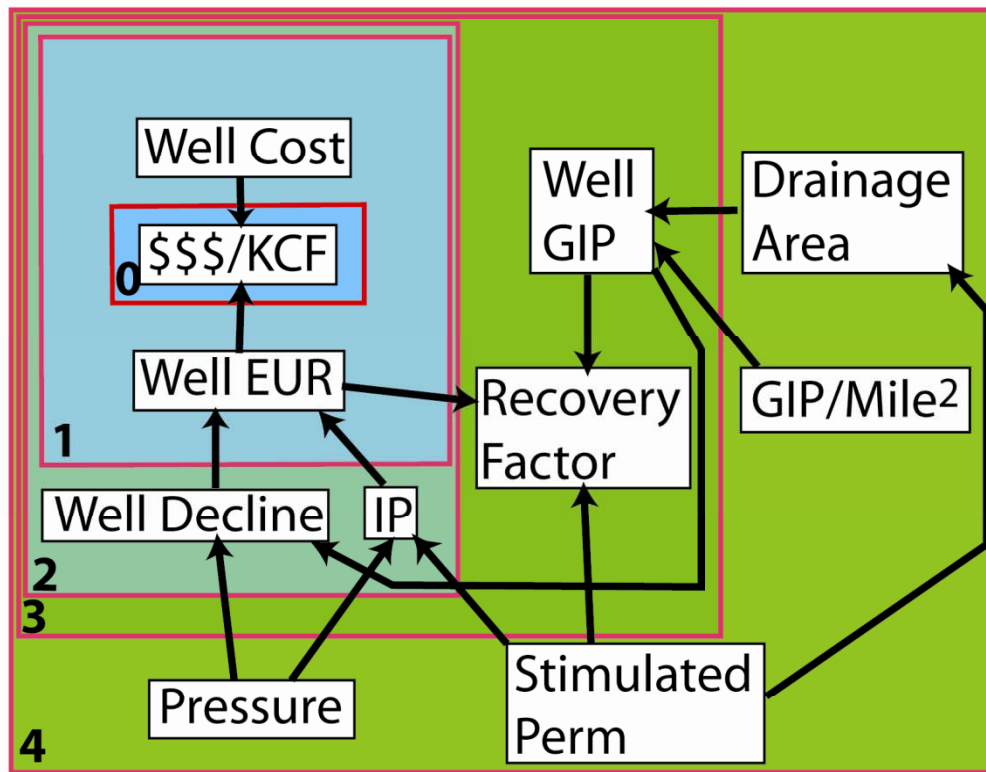

- In Unconventional Resources (Shale Gas, Tight Gas, and Coal Bed Methane) the hydrocarbon system elements are largely controlled by the properties of a single lithology or closely spaced groups of lithologies.
- The ability to commercially extract natural gas from Unconventional Resources represents the primary risk in these resource types, and the commerciality of a particular play varies spatially within the region of hydrocarbon occurrence.
- It is critical to identify and evaluate the commerciality of Play Fairways (aka Sweet Spots) and differentiate these fairways from non-commercial areas.
- Although the properties of a single lithology can control Unconventional Resource commerciality, the properties of that single lithology represent the complex interaction of sedimentation and basin/tectonic evolution.
- Unconventional Resources require artificial stimulation (generally hydraulically induced fractures) in order to produce gas at commercial rates.
- Understanding/predicting commerciality in Unconventional Resources therefore requires understanding of a complex natural system and how that system will respond to engineering intervention.

Exploiting the BBN: Linking to Maps

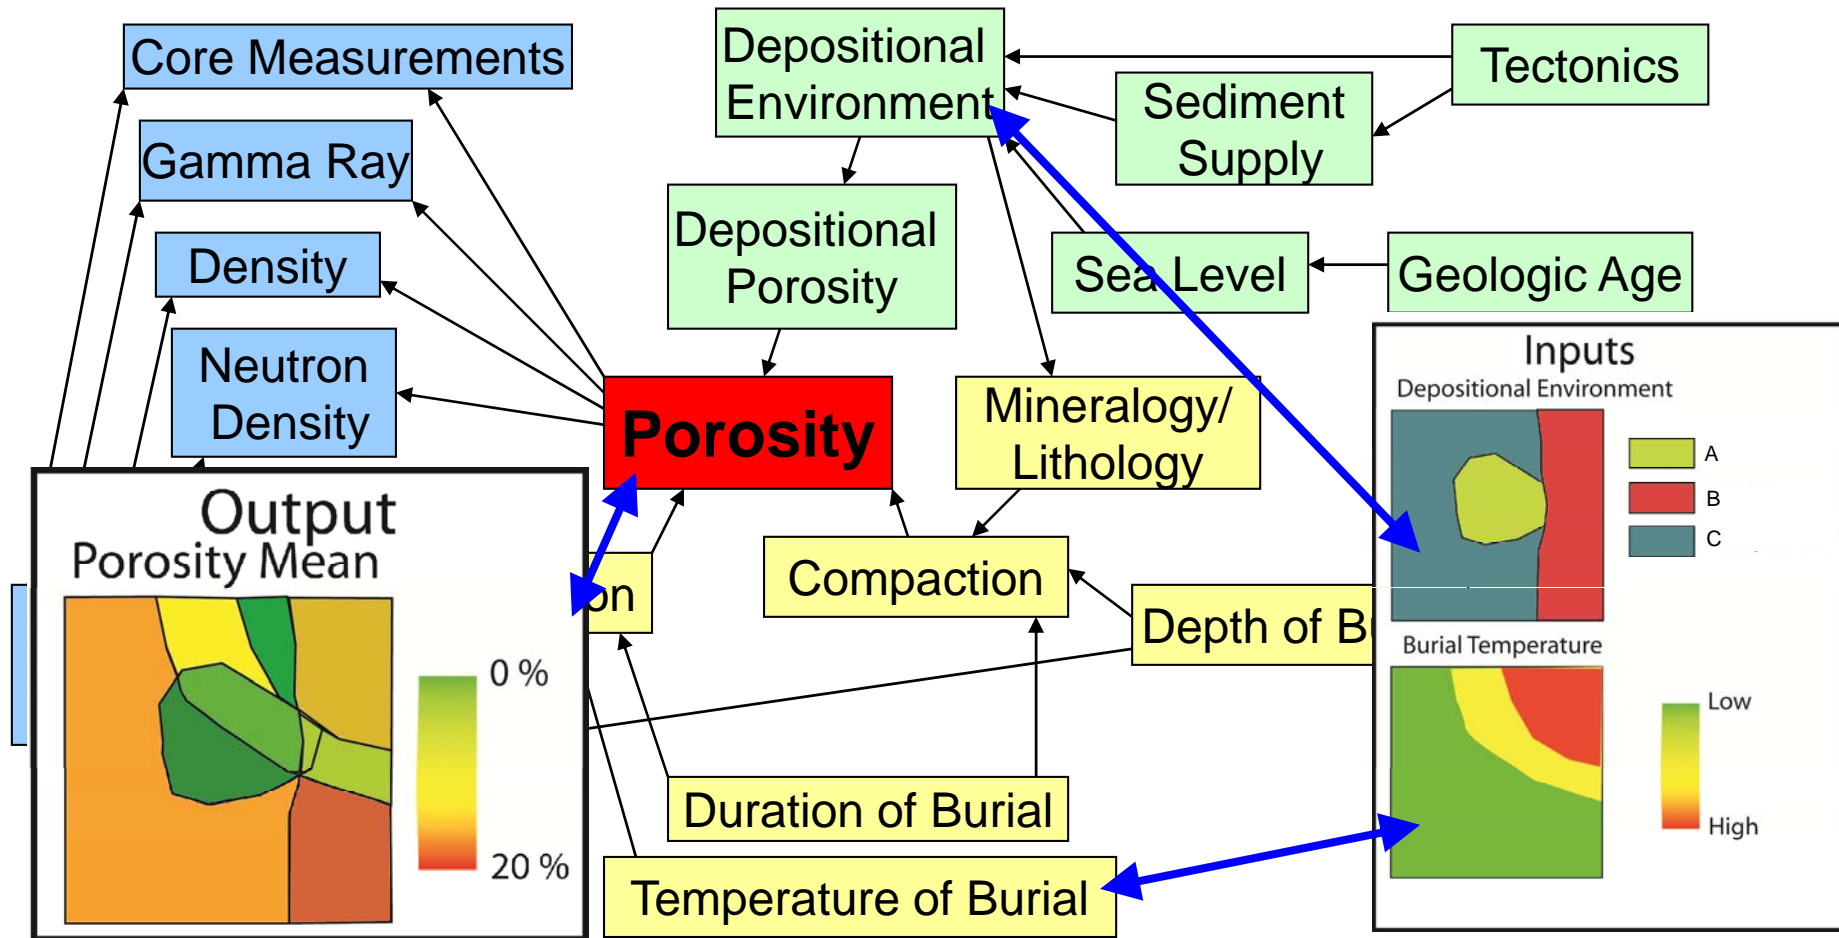

- To exploit the power of BBNs as a predictive tool, numerous tools that link BBNs to Geographic Information System (GIS) data have been developed within ExxonMobil.
- These tools:
 - Allow for output maps to be created based on BBN output and GIS based inputs
 - Visualize probabilistic output.
 - Aggregate probabilistic results to summarize resource estimates for areas of interest.
- A GIS enabled database of calibration data has been created that allows for the comparison of BBN predictions to actual results. These validation tools are used by the expert to improve predictive ability and gain insight into Unconventional Resources systems.

Leveraging the Belief Network: Linking to Spatial Data

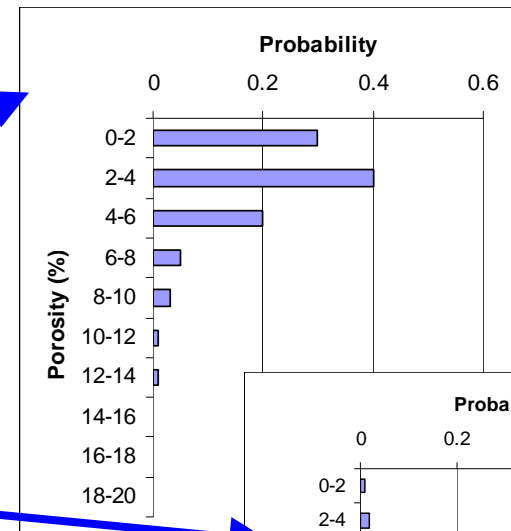

Leveraging the Belief Network: Linking to Spatial Data

Belief Networks Capture Uncertainty

Although maps typically show the mean, median or most likely value the full statistical distribution is available for analysis

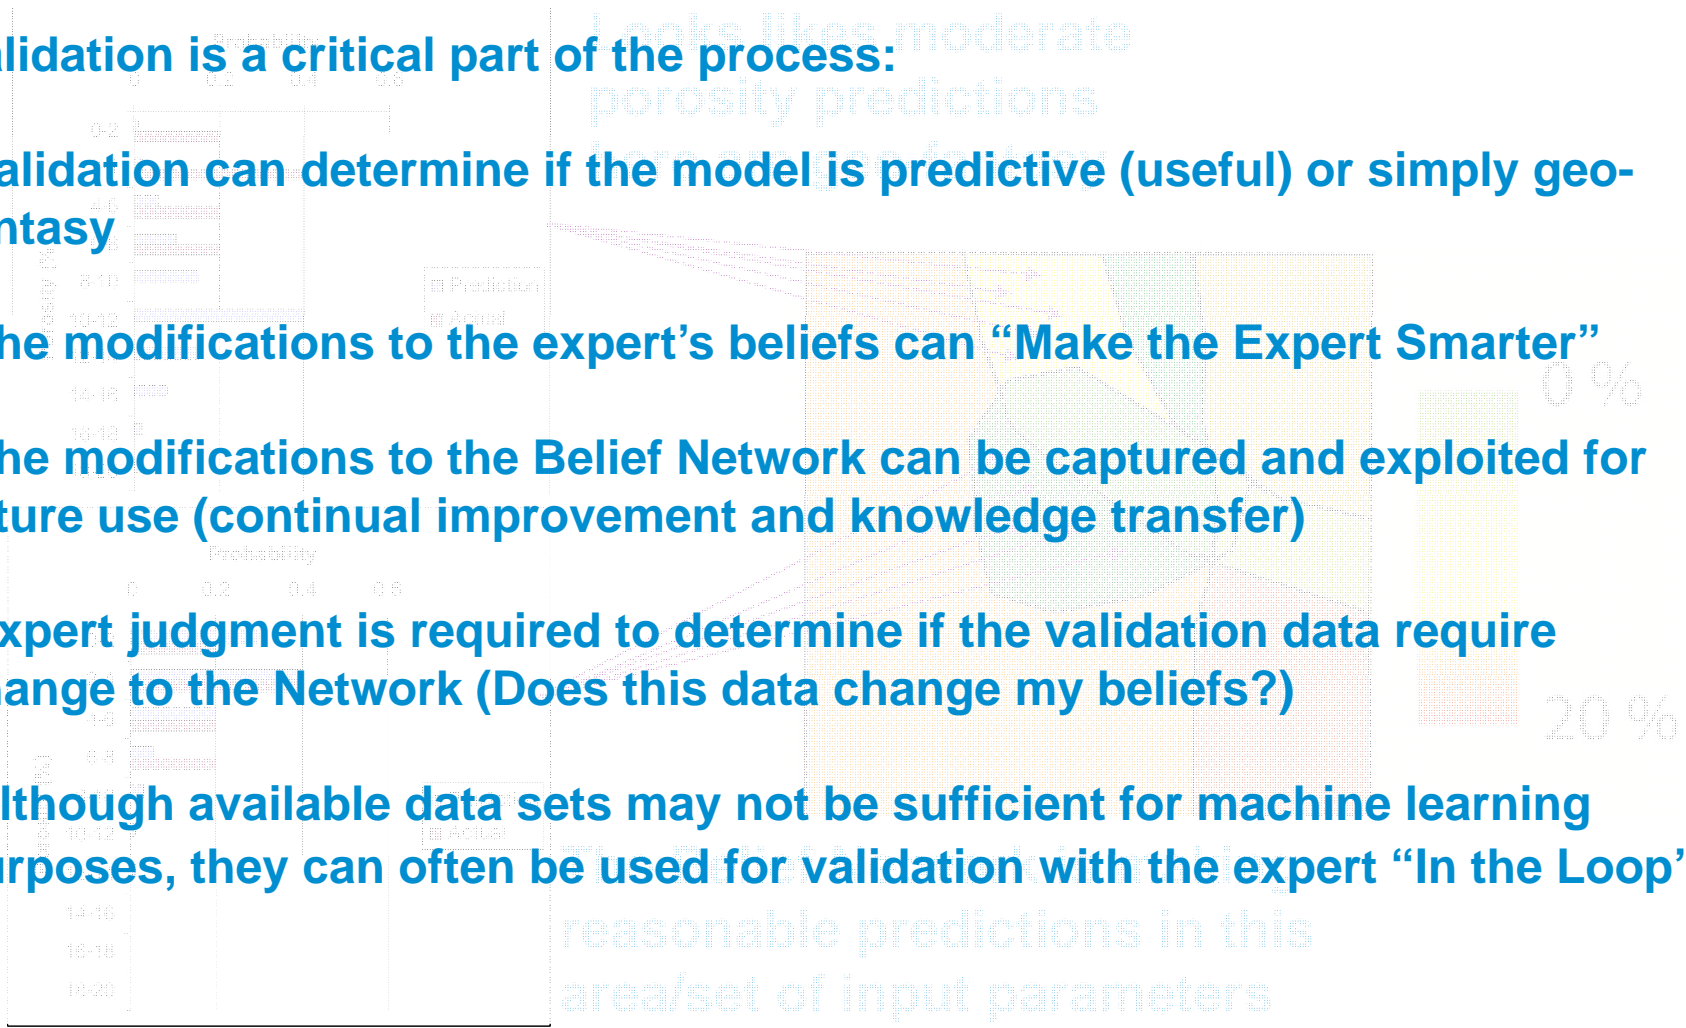

Spatial Linkages can aid in Calibration/Validation of Belief Networks

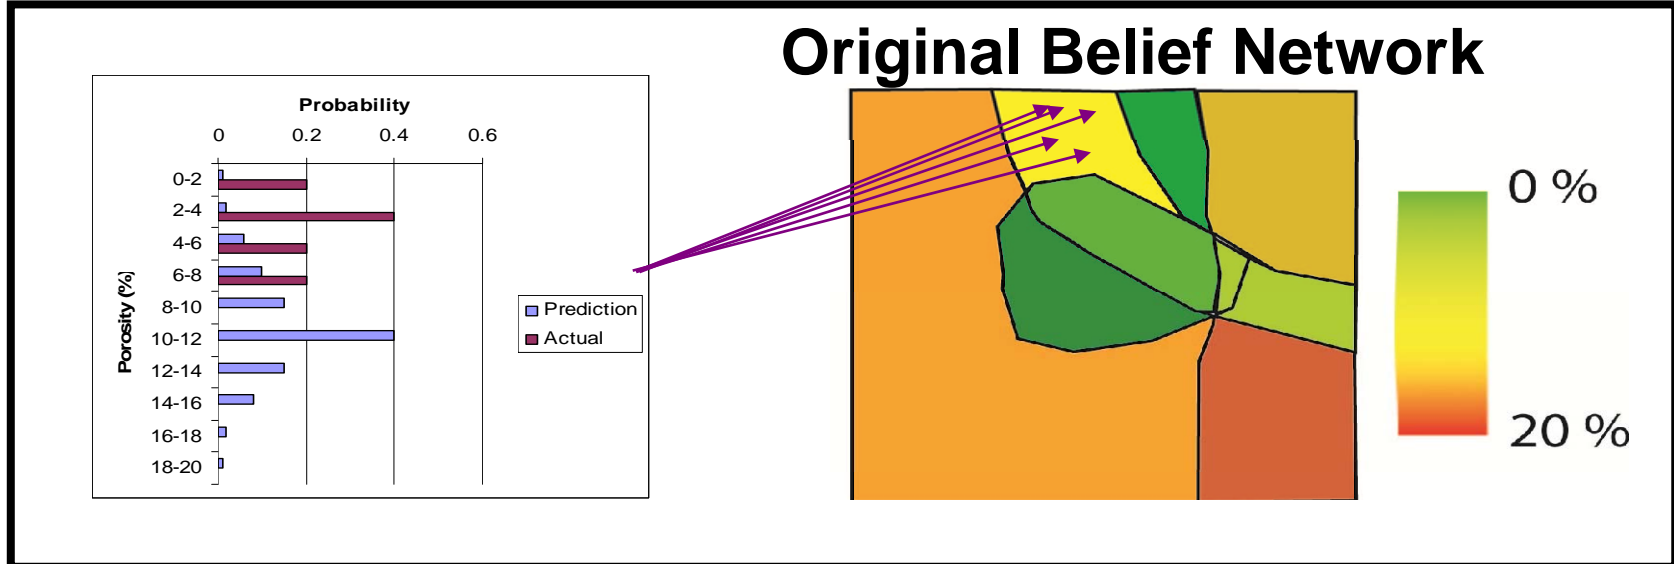

Validation is a critical part of the process:

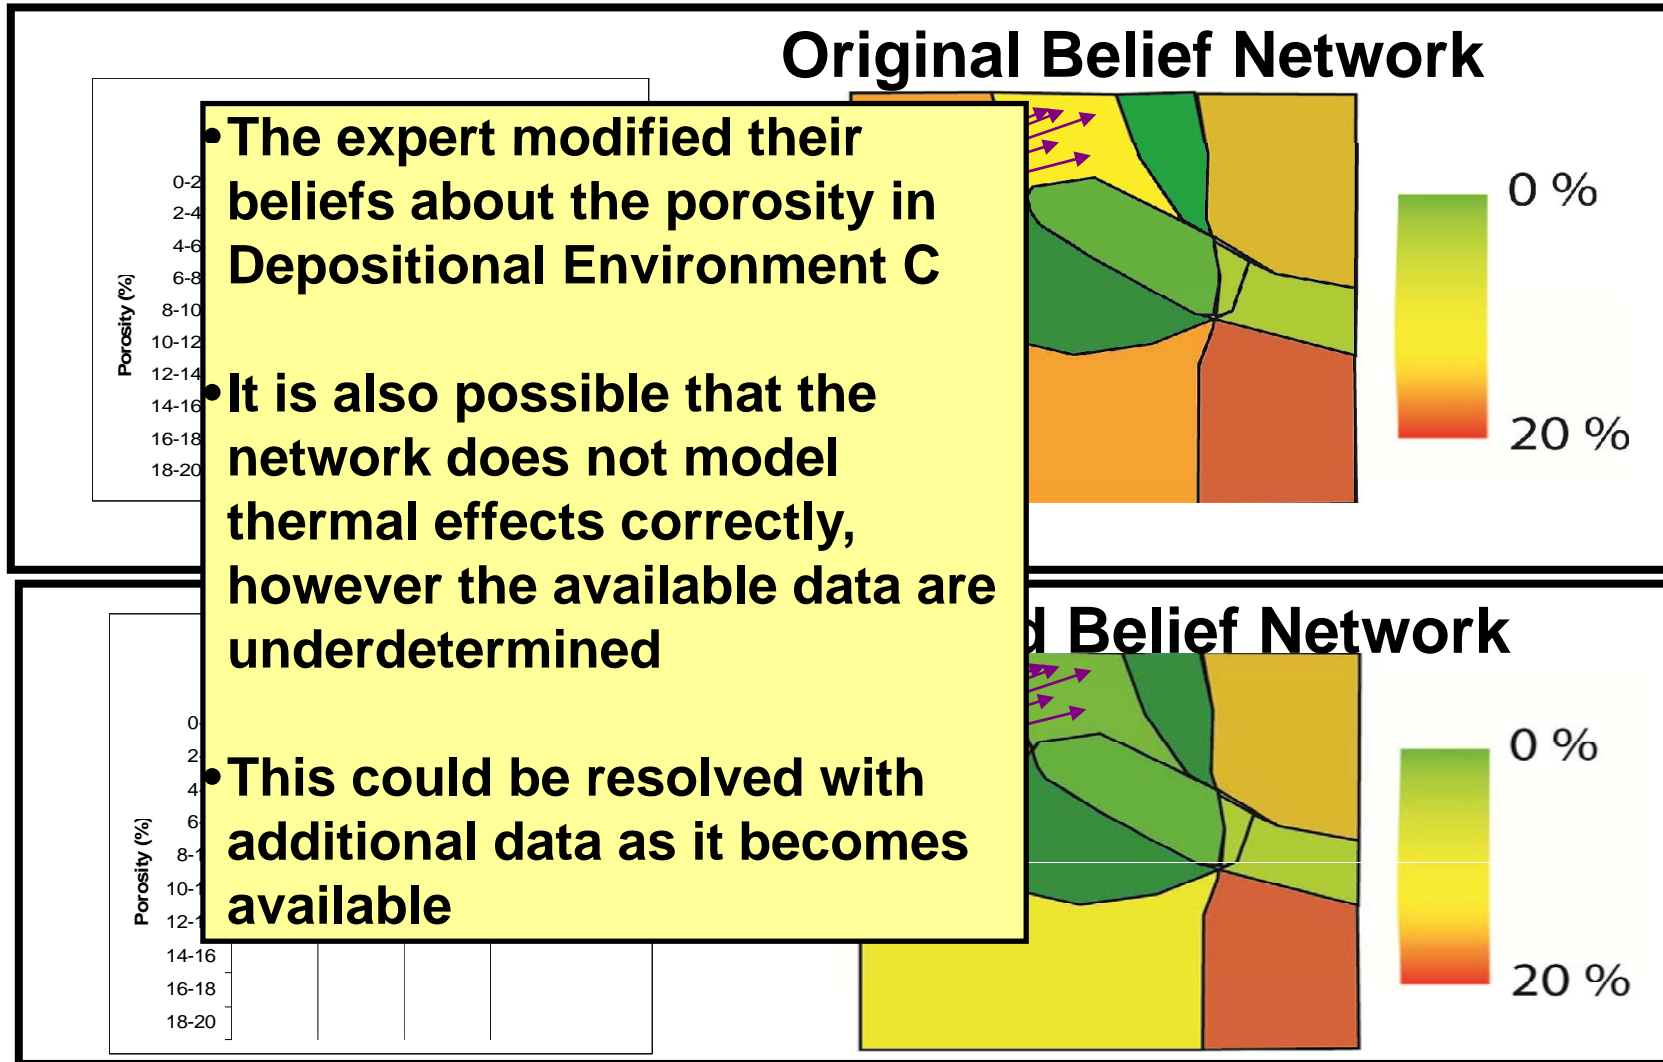

- Validation can determine if the model is predictive (useful) or simply geo-fantasy
- The modifications to the expert's beliefs can "Make the Expert Smarter"
- The modifications to the Belief Network can be captured and exploited for future use (continual improvement and knowledge transfer)
- Expert judgment is required to determine if the validation data require change to the Network (Does this data change my beliefs?)
- Although available data sets may not be sufficient for machine learning purposes, they can often be used for validation with the expert "In the Loop"

Comparing Plays

Conclusions

- BBNs provide an excellent tool to probabilistically model unconventional gas resources
- By breaking down the complex system in tractable pieces, different types of knowledge can be used to model different parts of the system.
- Validating the BBN is critical
- Linking BBNs to GIS systems provides an excellent opportunity to leverage the expert knowledge contained in the BBN and provides a rapid technique to evaluate continuous gas resources and the predictive capability of the BBN
