Abstract

The review of legacy data and the subsurface remapping of a ~4,000 km² area in the German Baltic Sea east of Rügen Island are reported. The area was previously explored by Petrobaltic, a consortium between USSR, Poland, and GDR (1975–1990); ~8000 km of 2-D seismic were acquired and four deep offshore wells (G14, H2, H9, K5,) were drilled. The area is located in a complex tectonic setting. It straddles four superimposed basins created by Caledonian, Variscan, and Permian events. All four contain potential reservoirs. They are overlain by non-prospective Mesozoic sediments. The Caledonian crustal domain contains the collisional boundary between the Precambrian continents of Avalonia and Baltica. It hosts Ordovician turbidites of the accretionary prism (H2, H9) thrusted northward onto the undeformed, starved Cambro-Ordovician foreland sequence on the Baltica shelf (G14). The Variscan Rhenohercynian basin contains Devonian continental clastic rocks associated with post-Caledonian rifting, covered by marine carbonates. These are overlain by Carboniferous marine carbonates and continental flysch related to the Variscan orogeny. The area also straddles the Gryfice graben (K5), a pull-apart basin linking the two branches of a 2000-km long, dextral-transtensional, Permian intracontinental rift. The graben Upper Carboniferous to Lower Permian volcanic rocks and clastic sediments. Younger marine Zechstein carbonates and evaporites form the northern margin of the Northeast German Permian basin which record late Early Permian thermal sagging that prevailed to the Early Cretaceous. The prospectivity of the area was re-evaluated by integrating 3320 km of re-interpreted, reprocessed seismic data with well data and field analogs from onshore East Germany and Poland. As a result, prospectivity domains based on structure and sediment distribution were mapped. In particular, the areal extent of potential Devonian and Carboniferous reservoirs is much larger than

mapped previously. It is shown that the historic wells were poorly placed and are not representative of the local prospectivity, and that undrilled structures with multiple, stacked targets exist in the area.

Purpose of Work and This Presentation

Work performed:

...to better understand the geology and therefore the prospectivity of the block and the surrounding areas

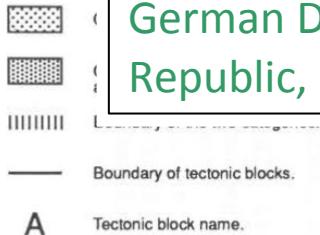

This presentation:

...aims to present the current status of hydrocarbon exploration on the German shelf east of Rügen Island

Figure 1.

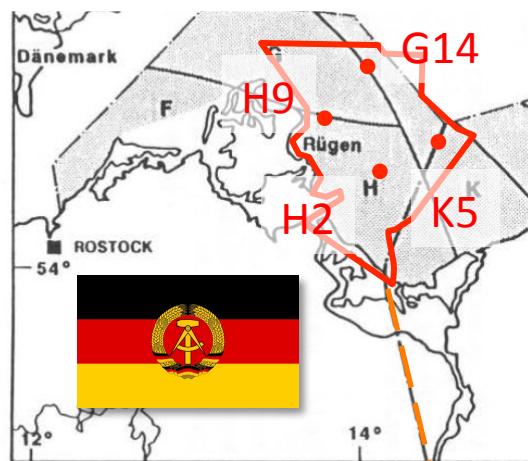

Petrobaltic (1975 – 1990) out of Gdansk:

German Democratic Republic, Polish People's Republic, Soviet Union

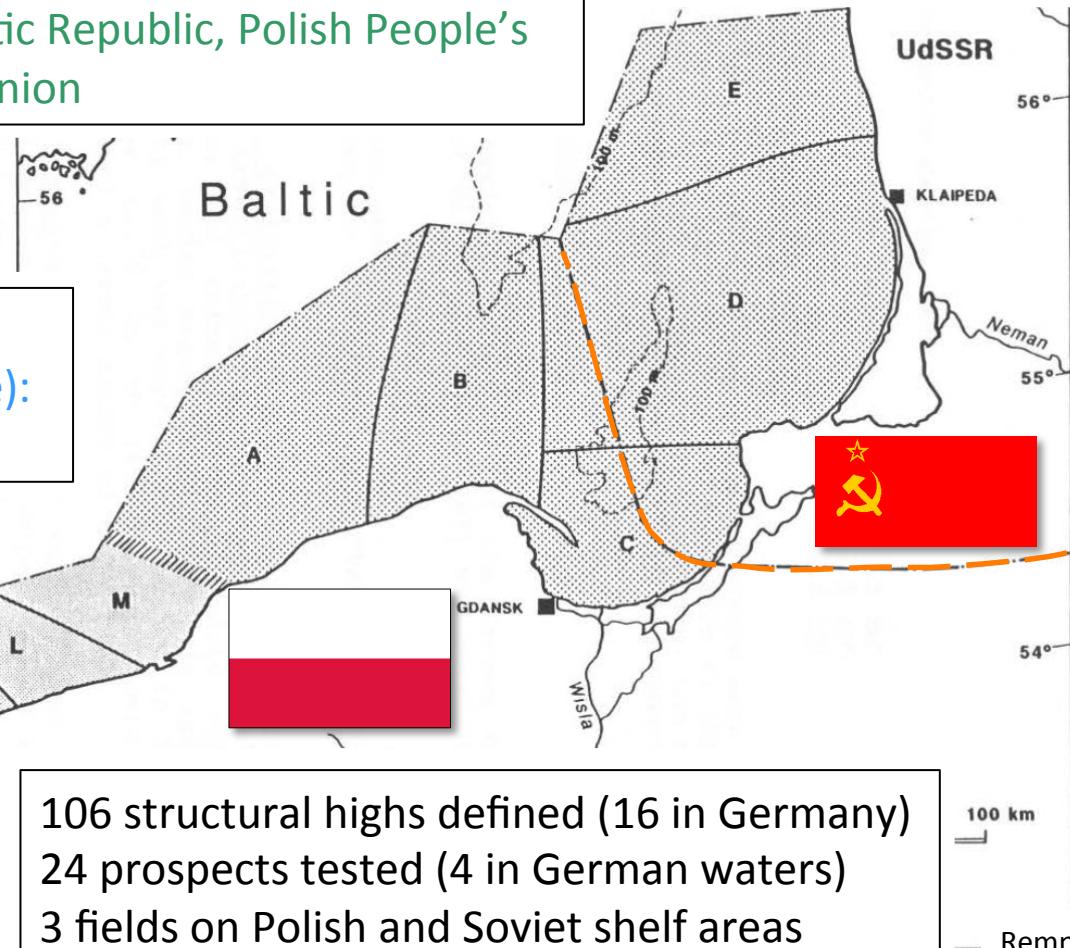

OKW

(Oderbank Kohlenwasserstoffe):
 4626 km² (CEP 2011)

106 structural highs defined (16 in Germany)
 24 prospects tested (4 in German waters)
 3 fields on Polish and Soviet shelf areas

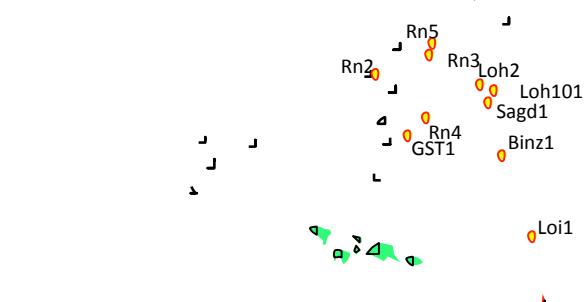

Exploration History

Onshore Pomerania:

- 4 oil fields in Cambrian sandstones (Baltica)
- 7 gas fields in Carboniferous sandstones
- 6 gas fields in Saxonian sandstones
- 11 oil fields in the Zechstein (Ca2)

Denmark

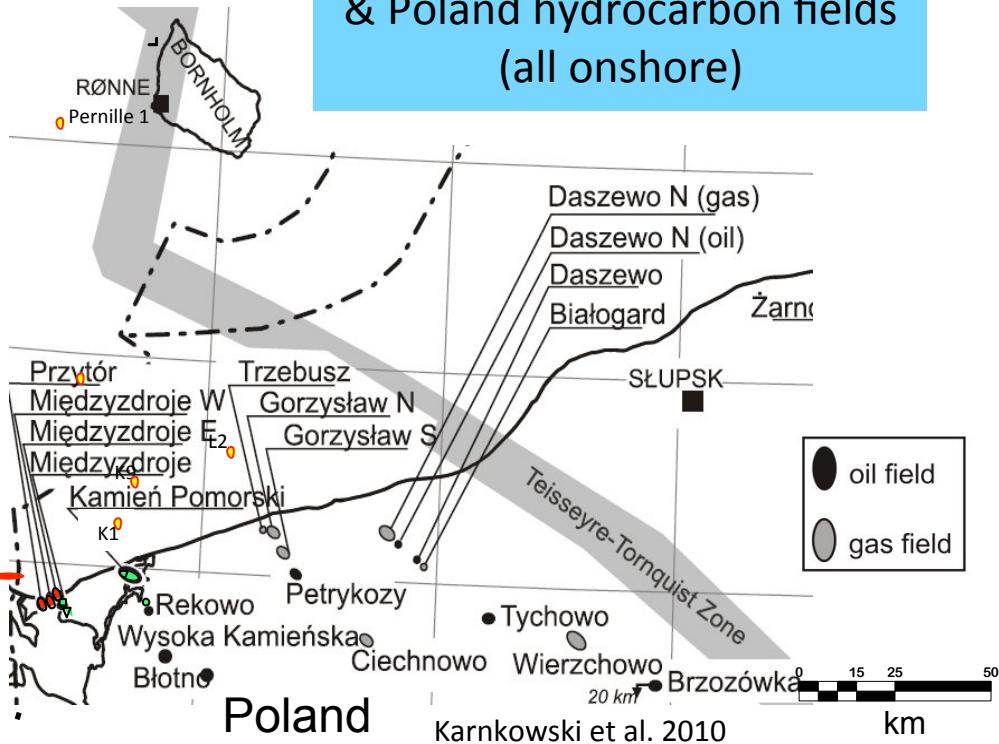

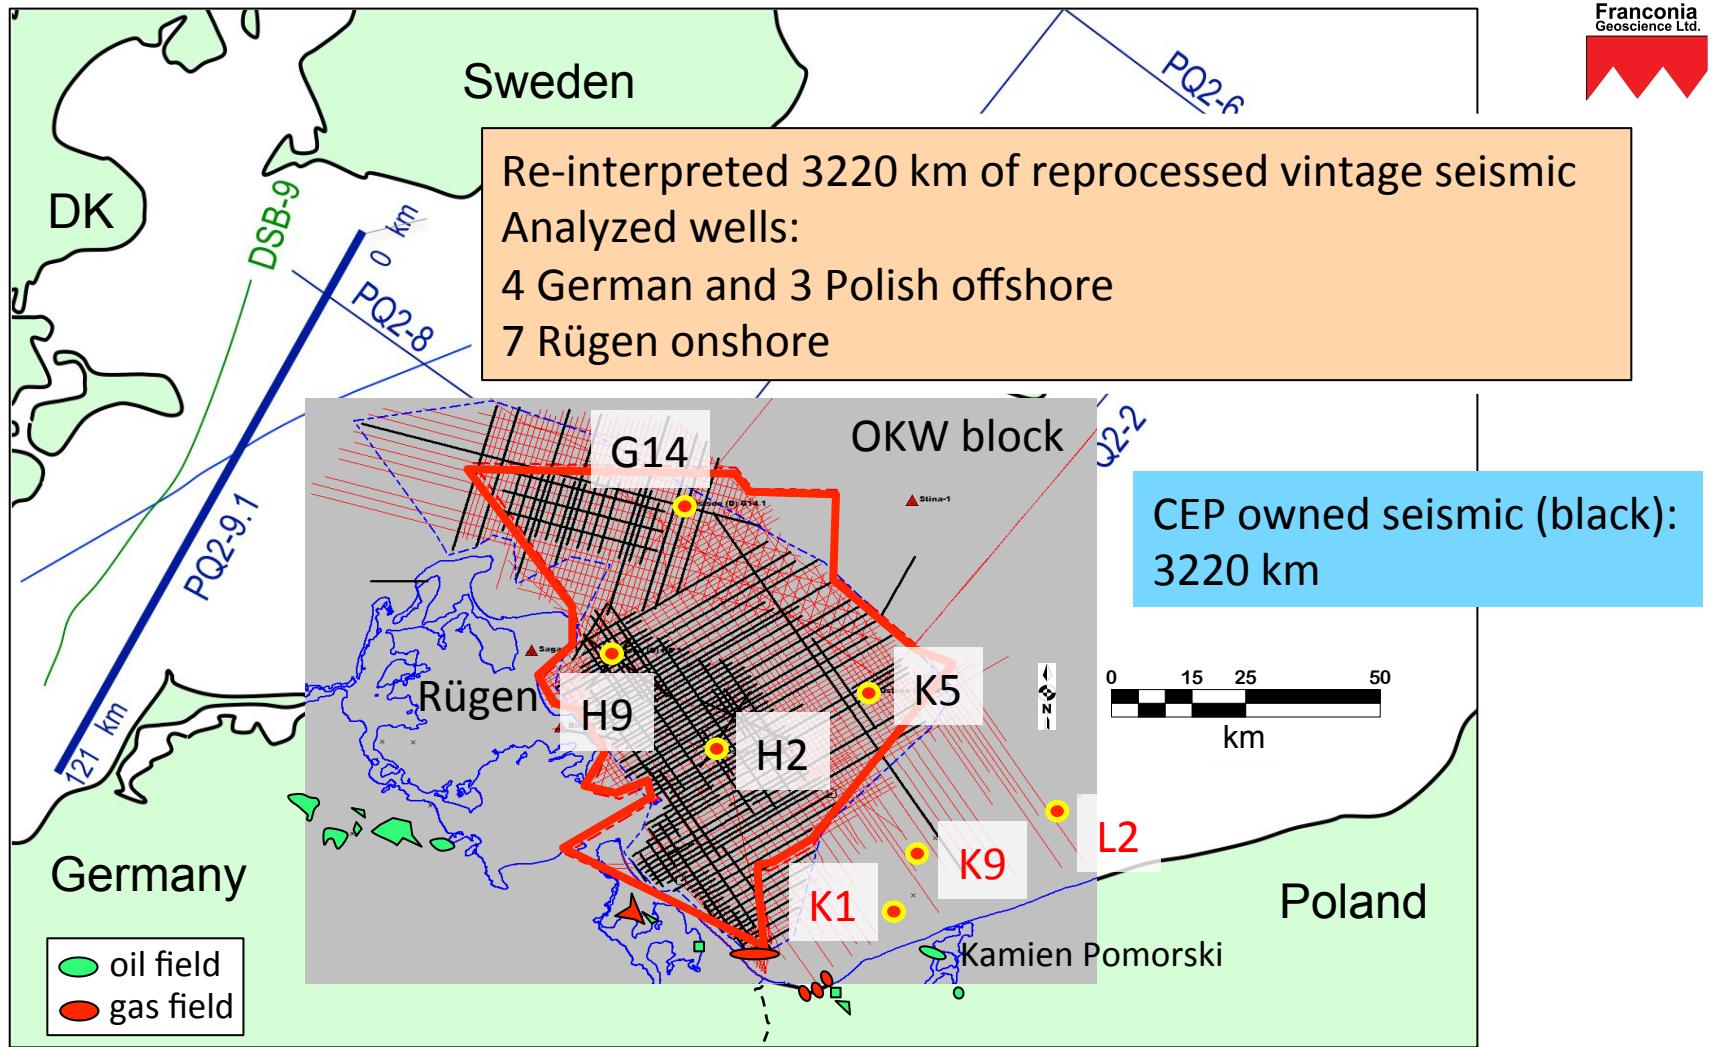

Germany

- oil field
- gas field

Concluding Remarks

Devonian and Carboniferous areal extent is much larger than previously mapped;
→ the newly mapped stack contains prospects and leads that need to be tested.

Upper Carboniferous and Zechstein have been identified as the main reservoirs.

Upper Carboniferous has a top seal issue that needs to be resolved.

Zechstein is best developed in the Gryfice graben and has unpredictable reservoir qualities.

Alpine inversion anticlines associated with NNW-trending TTZ-related faults are the main traps – they postdate early migration phases from Lower Paleozoic sources but pre-date late migration as well as Zechstein oil migration.

Prospects may be stacked: several targets can be tested with a single vertical well.

Additional seismic is required for key areas.
